# **ULTROPHOR**

Put wavy bands where they belong. Among yesterday's problems.

Banish wavy bands with Ultrophor, a unique new instrument designed exclusively for professional electrofocusers by LKB, electrofocusing pioneers since 1960.

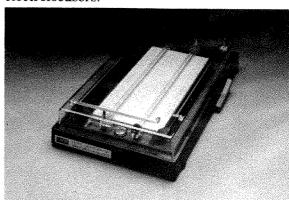

The ultracompact Ultrophor will cope with any analytical or preparative electrofocusing situation thanks to its radically new approach to electrode design, the construction of the highly efficient glass/aluminum cooling plate and the opportunity for atmospheric control.

The impressive list of bonuses include the flexibility of being able to run gels of any length up to 26 cm long or gels of any thickness, especially capillary-cast ultrathin gels, with less chance of wavy or skewed bands. The Ultrophor also has an unmatched capability to run high pH gels for sharp separations of alkaline samples as well as handle oxygensensitive or other labile samples.

Not only do you save valuable lab space with the compact Ultrophor but you save on time too because it's so fast and convenient to use and super-easy to clean. Like all LKB units, the new Ultrophor boasts a complete backup system and comprehensive technical support.

Contact your nearest LKB representative today for full information.

Ultrophor - the straight choice for professional electrofocusers.

# Atlas of Polymer and Plastics Analysis

Second, completely revised edition in three volumes

#### Volume 1:

#### Polymers: Structures and Spectra

By Professor Dr. Dieter O. Hummel, Cologne. XXXII, 671 pages, 1903 spectra, numerous figures and tables. 2nd completely revised edition. Hardcover. DM 475,-. Reduced subscription price, if all three volumes are purchased: DM 398,-.

#### Volume 2:

#### Plastics, Fibres, Rubbers, Resins

#### Spectra and Methods of Identification.

By Professor Dr. Dieter O. Hummel, Cologne. Part 1: Text. Approximately 200 pages. Part 2: Approximately 2800 spectra.

#### Volume 3:

#### **Additives and Processing Aids**

#### Spectra and Methods of Identification.

By Dr. Friedrich Scholl, Stuttgart. XXLV, 696 pages, 1355 spectra, 46 figures and 124 tables. 2nd completely revised edition. Hardcover. DM 520,-. Reduced subscription price, if all three volumes are purchased: DM 450,-.

#### **Contents Volume 3:**

Methods for the Analysis of Additives and Processing Aids for Plastics; Plasticizers; Inorganic Fillers and Pigments; Organic Pigments; UV Stabilizers and Fluorescent Whitening Agents; Antioxidants; PVC Stabilizers; Antistatics, Biostabilizers, Flame Retardants; Accelerators, Curing Agents and Activators; Processing Aids; Solvents; Bibliography – Spectral part – Index of Spectra – Subject Index.

#### **Subscription Offer**

A reduced subscription price is valid on orders for all three volumes.

Both parts of volume 2 will be delivered as soon as they become available in 1982. Volumes 1 and 3 will be delivered immediately after receipt of the order. The price for volume 1 is DM 398,— (individual price DM 475,—) and for volume 3 DM 450,— (individual price DM 520,—).

# Meeting heavy demands for lightwave transmission

The promise that emerging lightwave communications technology offered just a few short years ago is about to be fulfilled as telecommunications authorities the world over upgrade or expand their networks with optical fibre systems. And Philips technology has contributed much to this state-of-the-art.

For example, Philips originated and developed the plasma-activated chemical vapour deposition (PCVD) method of manufacturing high quality fibre possessing a refractive index profile closely approximating the theoretically desired parabolic form.

Unlike other CVD methods, PCVD employs a non-isothermal microwave plasma to stimulate low-temperature reaction of the gases  ${\rm SiCl_4}$ ,  ${\rm GeCl_4}$  and  ${\rm O_2}$  within a tube of pure silica glass. The plasma reaction zone is produced by a microwave resonator that passes to-and-fro along the entire length of the tube, a very even and thin layer of oxides being deposited at each pass. In this way many hundreds of layers can be deposited to achieve a graded index fibre profile that

An enlargement of the etched surface of an optical graded index fibre (50 $\mu$  core and 125 $\mu$  cladding diameter).

very closely resembles the ideal parabola.

Exceptionally high bandwidth measurements are obtained on continuous production runs of these fibres, typically 850 MHz per kilometer at 850nm wavelength, with a lowest value of approximately 600 MHz.Km, and a top value of 1200-1300 MHz.Km.

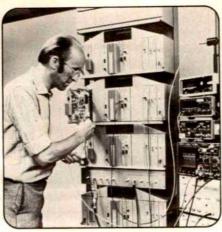

Philips also achieved a major breakthrough in the complex PCVD manufacturing process by speeding up deposition of the layers without any loss in fibre quality. Instead of the standard deposition speed of 0.2

gramme/ minute, new techniques enable speeds up to one gramme/minute to be reached, thus reducing the time taken to prepare silica glass preforms from 25 minutes to only five minutes per fibre-kilometer.

Increasing optical fibre quality at lower production costs is one of the many ways in which Philips technology is helping to meet the heavy demands for lightwave transmission. Here are some of the practical applications.

Overhead optical fibre cable now provides a cost-effective solution to the problems of television and FM radio reception in mountainous regions. A six-core NKF optical fibre cable system has been installed on a 2.8 kilometer pole-route to connect the villages of Aste and Beon, in the French Pyrenees, into the local CATV network. One of the first overhead optical fibre routes in the world, it provides the population of this remote area with FM audio reception and a choice of four colour television channels.

Lightwave telephone transmission. In addition to Philips all digital PRX/D exchanges, Saudi Arabia has ordered 140M/bits optical fibre systems to be integrated into the existing 2M/bits PCM networks in the Jeddah and Riyadh multi-exchange areas. Six-fibre cables, with a capacity of 1920 calls per fibre, will be used in the repeaterless routes, which total some 45 system kilometers. When completed it will be one of the first operational 140M/bits optical fibre transmission systems in the world.

Write for more information to your local Philips organization or to Philips, C.M.S.D.-Marketing Communications, VOp, Room 22, Eindhoven, Holland. Or telex:

35000-PHTC-NL/CMSD-Marketing Communications, Eindhoven, Holland.

I would like more information on:

Optical fibre detection. The Philips SEM505 scanning electron microscope employs a unique optical fibre detection system within the specimen chamber. In the backscattered-electron mode, the system achieves the highest possible detection efficiency for highlighting topographic and/or atomic number contrast. When used for cathodoluminescence detection, a light-gathering lens focuses the signal on the fibre bundle. Light impulses from the detectors are routed to photomultiplier/preamplifier combinations via optical switches. The system provides an exceptionally high degree of flexibility as well as a very fast reaction time. This ensures that TVrate images can be obtained, even at low accelerating voltages, in all detection modes.

#### Philips working on advanced technology

Circle No. 44 on Reader Enquiry Card.

From detection of monoclonal antibodies, through specificity determination and purification from ascites, BRL has the reagents to enhance all phases of your hybridoma-based research.

A complete system for the screening of hybridomas that secrete mouse immunoglobulins. The kit includes:  $\beta$ -galactosidase conjugated sheep anti-mouse IgG F(ab'), p-nitrophenyl- $\beta$ -D-galactoside as substrate, and complete protocol for use. In this enzyme-linked immunosorbant assay (ELISA), the second-antibody reagent has several advantages over alkaline phosphatase- and peroxidase-coupled antibodies:  $\beta$ -galactosidase is highly purified, and has a high specific activity. It is not present in most eukaryotic cells, and low background values are encountered when screening for cell surface antigens. Thus, sensitivity is enhanced. Also, p-nitrophenyl-β-D-galactoside does not show the potential carcinogenicity of other substrates used in ELISAs.

**BRL 9502 SA** 

#### **Immunoprecipitin**

Immunoprecipitin is formalin-fixed Staph A cells for the selective adsorption of IgG immunoglobulins. It specifically and tightly binds to the Fc portion of an IgG molecule and therefore will precipitate antigen-antibody complexes.

BRL® Immunoprecipitin is subjected to rigorous quality control assays to assure you a reliable high quality product. Its features include: High specificity and affinity for IgG immunoglobulins; 1 mg of Immunoprecipitin will bind ≥ 8 µg purified rabbit IgG ■ High stability for at least four months when stored at 4°C ■ Complete elution of the antigen from the absorbant for both analytical and preparative purposes Completé protocol describing the removal of loosely bound proteins to reduce contamination of antigen by bacterial proteins

**BRL 9321 SA** 

#### **Protein A Agarose**

BRL® Protein A Agarose is an affinity matrix prepared by covalently coupling purified Protein A to agarose beads. Protein A binds to the Fc portion of IgG molecules without interfering with ability of the immunoglobulin to bind antigen. This specificity permits the single-step purification of IgG antibodies and some IgM and IgD classes. BRI® Protein A Agarose is distinguished by: Stability over a wide pH range (2 to 11) Compatability with strong denaturants like guanidine hydrochloride and urea Actual lot analysis to determine the amount of Protein A bound to the gel (1.8 to 2.5 mg/ml of gel), and the binding capacity for human IgG (8 to 10 mg/ml of gel)

**BRI 5918 SA**

# RELIABILITY

# through Barr & Stroud technology at work

The equipment of TV broadcasting stations is designed, built and operated to ensure the highest quality output.

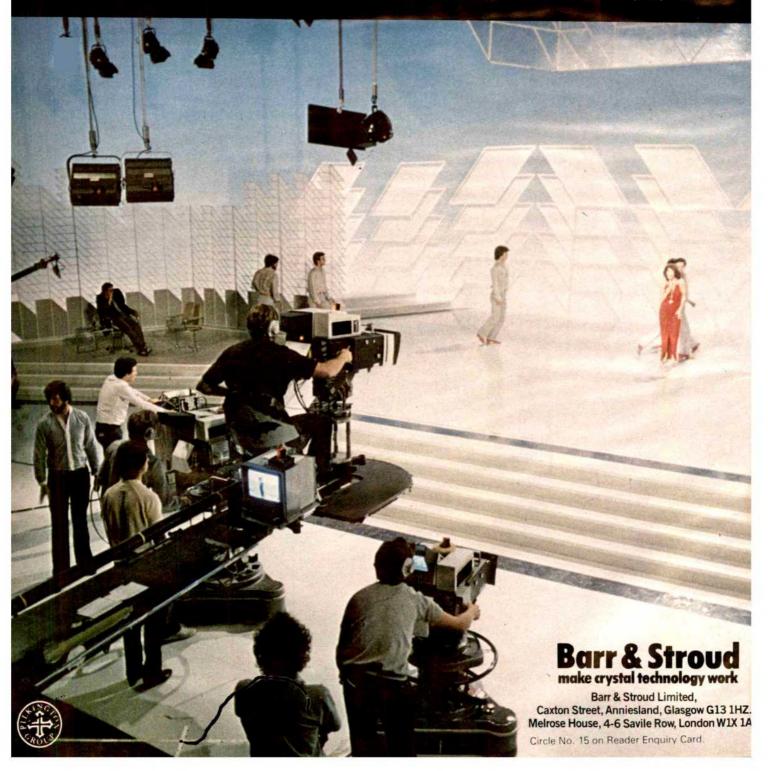

Mullard surface acoustic wave filters for TV receivers ensure accurate, reliable and stable reproduction.

Unlike conventional TV IF bandpass filters, they have characteristics accurately determined by their design, require no adjustment, and have lifetime stability. In addition to the obvious benefits to TV setmaker and viewer, they offer the advantage of coping with the exacting standards of Teletext.

Barr & Stroud enter the picture as the only UK producer of lithium niobate, a grown crystal material used as the substrate for surface acoustic wave filters.

The production of this exotic material, to vigorous quality standards, is another example of Barr & Stroud's leadership and innovation in today's technologies.

Because of our serious commitment to research and development, engineers and designers everywhere can rely on our expertise to solve their most complex problems.

#### **Nature Binders**

Keep your copies of *Nature* protected in these tough black PVC binders

- Each binder is supplied with a set of wires for the easiest possible loading
- Nature logo blocked in gold on spine
- Transparent plastic pocket provided for your own reference
- Each binder takes two volumes of Nature; three binders will serve for a year

#### Prices (including postage):

Single Binders: UK, £4.00; Rest of World, \$10.00

Set(s) of 3 Binders: UK, £10.00; Rest of World, \$25.00

Orders (with remittance) to: Nature, Macmillan Journals Ltd., Brunel Road, Basingstoke, Hants RG21 2XS, UK

#### How Britain runs its Science

#### How the US runs its Science

# These two new *Nature* wallcharts are now available.

The 610 x 915mm guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from *Nature's* offices in London, Basingstoke and New York.

Now you can choose the most suitable microcarrier for your culture

Cytodex microcarriers bring new opportunities to

- routine and experimental cell culture
- production of viruses, interferon and other cell products
- in vitro studies on differentiation and metabolism

Cytodex 1

The microcarrier proven to be effective for growing more than 100 different cell types.

NEW Cytodex 2

Especially developed for better yields of viruses and cell products. Retains all the advantages of Cytodex 1 with the added benefit of new charged groups necessary for cell attachment localized only on the surface of the microcarriers.

The latest concept in microcarriers. The stable collagen surface gives improved attachment and yields of many cell types, especially those normally difficult to grow in culture. Enzyme digestion of the surface gives improved recovery and viability of harvested cells.

Make the most of your cell cultures. For more information on how Cytodex microcarriers give you new opportunities in cell culture contact us today.

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name artwork should be unlettered. Suggestions for cover illustrations are we and the figure number. Original ne. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published

#### INTERNATIONAL **JOURNAL OF SOLAR ENERGY**

edited by Wolfgang Palz Head of the Solar Energy Research Programme Commission of the European Communities. Brussels

We invite you to submit reports of original work on any aspect of solar energy for this forthcoming journal from Harwood Academic Publishers. To be published next Spring 1982, the journal will bring together the full range of experimental and theoretical research now being carried out in Europe, North America, Japan, and the developing nations around the globe. To gain a better idea of the scope of this new periodical, please consult the list of editors and their special interests (shown opposite). The contents will cover all phases of solar energy such as photovoltaic power, biomass, solar heating in dwellings - active and passive solar heat for desalination, ponds, etc., systems using optical concentration, photochemical and biological conversion processes, wind generators, wave power, ocean power, and radiation data.

From time to time issues devoted to a single topic will also appear. Letters, news items and technical notes will be regular features.

For helpful NOTES FOR CONTRIBUTORS please write to the Publisher at the address below.

Probability and Statistics; Segregation of Alleles; Assortment of Non-Alleles; Linkage, Recombination and Mapping; Mating Systems; Appendix 1 - Mean and Variance of a Binomial Distribution; Appendix 2 - Estimation of a Parameter Appendix 2 — Estimation of a Parameter by the Method of Maximum Likelihood; Appendix 3 — Extensions of the Method of Maximum Likelihood; Appendix 4 — Comparative Efficiency of Matings for Detecting and Measuring Linkage; Appendix 5 — the Fibonacci Sequence; Appendix 6 — Systems of Mating; Appendix 7 — Numbers of Mating and Numbers of Mice per Mating; Appendix 8 — Nomenclature; Appendix 9 — Record Keeping; Appendix 10 — Mouseroom Layout and Procedures; Glossary of Signs; Literature Cited; Index. Literature Cited: Index.

This book is a primer and reference on probability, segregation, assortment, linkage and mating systems for biomedical scientists who breed and use genetically defined laboratory animals for research.

It is organised so as to be useful to 'novices' and 'experts' alike. The former will find an orderly former will find an orderly development of the probability aspects of transmission tests, segregation analysis, allelism tests, independence tests, linkage analysis and mapping. They will see how to design genetic experiments to yield data which can be analysed and they will also find a clear exposition of the theoretical consequences of various breeding systems which will enable them to make rational choices as to the kinds of animals to use in their own

Experts will find that the most frequently used formulae needed for estimating various genetic parameters and their random sampling variances are assembled in tables or are clearly set forth in the text and that the extensive table of contents and detailed index will enable them to find the necessary formulae quickly.

LEVEL: Professional, graduate, undergraduate reference.

# **Nature** announces the first wall chart showing how the U.S. runs its science ... shows who makes U.S. science decisions, who gets the money, and how it's spent

If you're involved in making decisions about science, or if you're looking for your share of science funding, you need Nature's new 1981 guide to how the nation spends its science dollars and who controls that money.

Compiled by Nature from literally hundreds of sources, the wall chart offers data on actual dollars spent on science by government agencies, industry, foundations, universities, research and medical centers. The chart lists key U.S. government policy makers, with their addresses and phone numbers.

Most significantly, the chart shows the interlocking relationships within the science, engineering, and medical establishments.

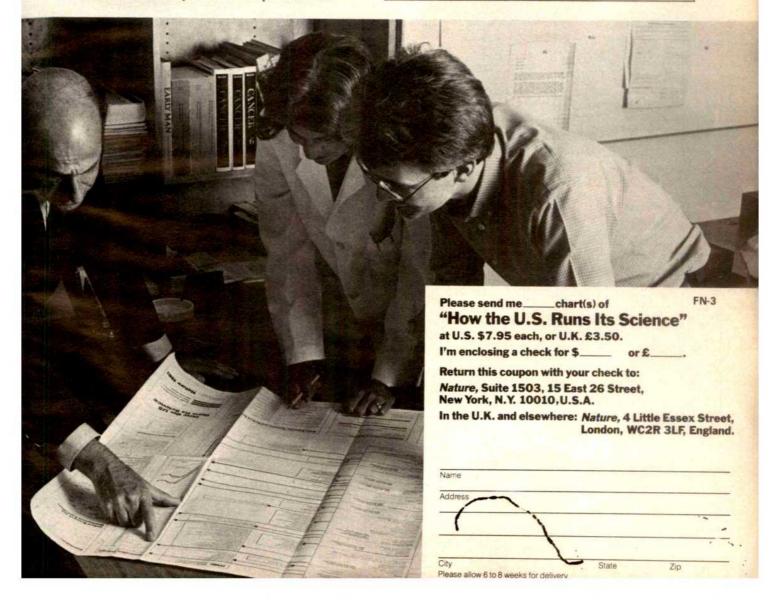

Designed as a fold-out that you can carry to meetings, or for hanging as a 2 x 3 ft. wall poster for permanent reference, the chart enables you to answer questions that

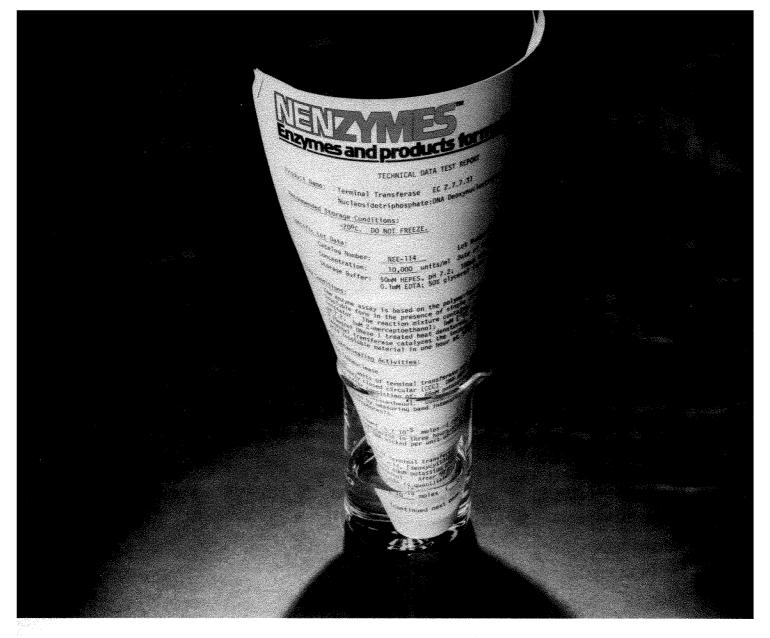

might otherwise take weeks of research to dig out. Compact, color-keyed, and handy, it will be an enormous aid to you and your colleagues. We strongly urge you to order sufficient copies to cover the needs of your entire staff or department.

#### "How the U.S. Runs Its Science"

another authoritative publication from Nature, for more than 100 years, the world's most respected source of science

## Before we call them ultra-pure, they have to get their feet wet.

NENZYMES™ is not simply a title bestowed on our ultra-pure enzymes and related products for DNA-RNA research. It is an award for performance.

NENZYMES must perform as standards in our routine biological testing programs for <sup>32</sup>P- and <sup>3</sup>H-labeled nucleotides, as integral components in our nick translation and end labeling systems, and as standard tools in our cloning laboratory. Even to qualify for this work each lot

is first subjected to numerous specific assays (which are recorded for customer inspection).

So if NENZYMES weren't biologically pure we'd soon find out. We're just as insistent on trouble-free system performance as you are.

That's why it makes sense to buy your enzymes from systems people. Call us for complete NENZYMES specifications and ordering information.

# The fraction collector that turns science fiction into science

Just a few years ago no one would have believed that a fraction collector like SuperRac could exist. Most researchers were used to their constant-volume and constant-time collectors – with level-sensors at best.

Many were resigned to a compromise between resolution and the efficient use of collection vessels.

SuperRac will change all that.

To begin with, SuperRac has built-in slope detection. Unlike a simple level sensor, it cuts peaks at their true beginnings and ends. You can even collect unresolved peaks in well-resolved fractions . . . and you never need to worry about baseline drift.

SuperRac also diverts uninteresting eluate to a waste trough – via a valve –

so you use fewer test tubes.

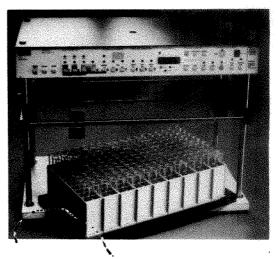

SuperRac's memory stores five different collection procedures that you can recall at the touch of a button. It has nine time windows allowing you to limit collection to interesting parts of your chromatogram.

SuperRac automatically compensates for asymmetric peaks and peak-width broadening during an isocratic elution. And it continues to run the pump for a specified time after a collection to clean and equilibrate the system.

Ask your local LKB distributor for more information on the new SuperRac. He'll give you several more reasons why we named it Super.

# TO YOUR TON

#### What Mr Blix should do

UN's atomic energy agency has been through a bad patch. Its new director should resurrect its original purpose.

The International Atomic Energy Agency in Vienna has plainly been scarred by the events of the past year, the Israeli raids on the Iraqi reactor at Tamuz among them. But for most of the year the agency has also been haunted by the unaccustomed difficulty of deciding who should be its new director general. Dr Sigvard Eklund, who until September had held the post for eight years, had not simplified the transition by making no secret of his willingness to serve for a third term: but the agency's governors were also perplexed in choosing between the two candidates on offer — Mr Hans Blix, deputy foreign minister of Sweden and Mr Domingo Siazon of the Philippines. The difficulty has been largely that of choosing between candidates from developed and developing countries. Exactly the same problem has more recently cropped up in the United Nations itself. The upshot of six months' heart-searching in Vienna is that Mr Blix has now taken up the post of director general. But he will probably be challenged again when his term expires four years from now. The danger is that the agency, hitherto almost as free from politics as the World Meteorological Organization, will fall foul of the squabbling to which most other United Nations organizations are prone. Mr Blix should therefore bend his energies to the insulation of the agency from the petty endemic politics of the United Nations system.

How is this to be accomplished? A sense of history will help. The Vienna agency is the product of President Eisenhower's programme in the 1950s that rejoiced in the slogan "Atoms for peace". Nobody doubted, then, that nuclear power stations would spring up apace in the territories of the nuclear powers, bringing prosperity in their wake: what more natural, even at the height of the Cold War, than that the United States and the Soviet Union should offer to share the benefits of their new technology with less fortunate governments? Even in the 1950s, however, people had forgotten that the agency they created had only its name in common with the much grander concept put forward in 1947, as part of the Baruch plan, of a United Nations agency that would literally be the sole owner and custodian of fissile material. The agency that Mr Blix has inherited is best known as the entity responsible for the administration of the safeguards required of non-nuclear power signatories of the Non-Proliferation Treaty: programmes of technical assistance continue, but on such a modest scale that they can make very little difference to the expectations of non-nuclear states that they will be able to decide for themselves even such simple questions as whether the much disputed benefits of nuclear power apply to them. The unaccustomed quarrelsomeness that has now emerged among the 111 member states at Vienna owes something to the belief that the agency should be doing more to spread such benefits of nuclear power as there are. The discontent is entirely justifiable.

The agency's most urgent need is for a realistic programme for helping developing countries to make sober appraisals of the utility of nuclear reactors. There is a limit to the extent to which they can be fobbed off with technical advice from international consultants on the place of nuclear technology in, say, agriculture. But where, the agency will ask, are the funds with which to support a more ambitious programme? For the time being, the unwillingness of the chief members of the agency to contribute more towards its budget is not its chief impediment.

At frequent intervals in the past two decades, the agency has published assessments of the place of nuclear reactors in the

economies of developing countries whose optimism has been matched only by their naivety — and which have nevertheless contributed to the present sense that the major nuclear powers are malevolently keeping nuclear power to themselves. Mr Blix should begin by commissioning a more realistic (and more technical) appraisal of the place of nuclear power in the smaller member states of the agency. He should then go further, for the assessment would almost certainly conclude that, within a decade, a great many smaller states will be able to make good use of the occasional well-sited and well-designed power reactor; he should offer a technical appraisal service for developing countries unable to decide between the claims of rival reactor salesmen.

Naturally, many of the founder members of the agency will object to such proposals. Appraisals that are too realistic may persuade some customers that the time has not yet come when they should buy. In the long run, however, that can only benefit the reputation of nuclear power and thus of its application. Others will protest that the encouragement of nuclear power can only assist the proliferation of nuclear weapons. The reply is twoedged. First, the involvement of the agency in the provision of civil nuclear power is likely to ensure that the safeguards procedures are effective. Second, the Non-Proliferation Treaty is a bargain in which non-nuclear powers agree to forsake nuclear weapons in return for a promise by the nuclear powers that they will assist with civil development. There is no way in which the nuclear powers can escape the commitment except by abrogating the treaty. Their best course is to help ensure that the safeguards procedures are continually improved.

To this end, Mr Blix could usefully consider whether the agency should soldier on as an amalgam of an international regulatory agency and a technical assistance organization. There is a strong case for reconstituting the safeguards organization as an independent quasi-judicial entity, perhaps a kind of permanent secretariat of the Non-Proliferation Treaty. Four years from now there will be a review of the working of the treaty. If safeguards are to be reorganized by then, it is not too soon to start. Fortunately, the wind is blowing in the right direction. The United States Administration is ready to loosen its restrictions on the export of reactors, but would find it convenient if the safeguards procedures were at the same time made more explicit. The agency's committee on the security of supply of nuclear materials, set up after the abortive conference in 1980 on the working of the Non-Proliferation Treaty, needs something tangible in which to sink its teeth. And with Mr Blix being a newcomer there is an ideal opportunity for change.

#### Congress versus cancer

The US Congress would legislate against cancer. It must be patient.

Part of the strength of democratically elected bodies, the United States Congress included, is that they are not necessarily bound by the decisions or the prejudices of their predecessors. That, however, is not a sufficient explanation of the way in which the present United States Congress, still less than a year old, seems bent on repudiating its predecessors' fondness for those agencies in the front line of what many congressmen used to call the "war

against cancer". Yet it is less than ten years since President Richard M. Nixon and Senator Edward M. Kennedy were vying with each other to devise still more generous programmes for cancer research. Over the years, the National Cancer Institute, a constituent of the National Institutes of Health, has been the centre of most of this attention, with the result that its operating budget now exceeds \$1,000 million a year. But something has gone wrong. Now hardly a week seems to pass without the director of the institute, Dr Vincent T. DeVita, appearing before one investigative committee or another to defend his institution against some fresh set of allegations. What can be the explanation? Has Congress fallen out of love with the war against cancer, or is there a more sinister explanation?

Part of the trouble is that Dr DeVita is new to the job — he took up his post only at the beginning of the year — and better known as a scientist than as a politician. Indeed, it seems that he has concentrated in the past few months on bringing a sense of direction to the research programme that he is paid to direct. This part of his job seems to have been done with such flair that when, earlier this year. Senator Hatch's committee sought to saddle him with responsibility for the earlier maladministration of research grants, a group of Dr DeVita's colleagues wrote expressing their admiration for their new director. Nobody would be surprised, however, if in the course of spending more than \$20 million a week on research, Dr DeVita has neglected to pay court as assiduously as he might to those who hold the purse strings in Congress. Or is it that Congress, like the National Institutes of Health, is waiting to see if the new director will turn out to be a political appointment, the Administration's representative within the institutes and not the institutes' means of interceding both with the Administration and with Congress? It goes without saying that a political appointment, a sharp break with precedent, could be disastrous for the National Institutes of Health, whose most urgent collective need is coherence and not further partition.

Dr DeVita's problems are nevertheless substantial. Accusations earlier in the year that some research grants had been used and administered in such a way that data of doubtful value had been gathered appear to have been substantiated. Neither then nor since, however, has Congress asked itself whether such incidents, acknowledged to be rare, can be avoided in such a gigantic programme for throwing money at the problem of cancer. Much of the same is true of last week's hearing in the House of Representatives, when Dr DeVita was required to deal with newspaper allegations that cancer patients treated with novel drugs within the framework of agreed experimental protocols had died as a result of the drugs rather than of the diseases the drugs might, with luck, have treated. How else, it might be asked, can novel drugs be tried in human beings? This week, Senator Paula Hawkins will return to the same charge; she has been asking, ever since she reached the Senate in January, why, a decade after the war against cancer was conceived of, people still die of all but a few forms of the disease. It is to be hoped that Dr DeVita and his colleagues will have the courage to tell Senator Hawkins the truth. The war against cancer was misconceived. The idea that such a problem might be made to go away by spending money was always destined to end in disillusion. From the start, it has been plain that while even successful methods of treatment lack a sufficient basis of understanding, they cannot be generalized. Yet, it must also be made clear, developments in the past few years promise substantial steps in the right direction, whatever that may

The practical consequences of such a confession on the part of the National Cancer Institute need not be as disastrous as they might seem. Congress may (separately from this week's proceedings) reduce the budget earmarked for the institute. It may have no choice. But the cancer institute would be more easily managed, and would be more effective, if it were forced to be more discriminating, at its very generous margin, in how its funds are spent. And the enterprise that it represents would be much less vulnerable than at present to the constant sniping that now afflicts it if both Congress and the United States public understood more clearly that they must be patient.

#### **Shame on New York**

Baseball has become a game of chance. How should it be reformed?

The city of New York has had a bad week. The leading article in last Thursday's New York Times was understandably entitled "The shape of New York's shame". Oddly, however, the newspaper was castigating the city council for a piece of flagrant but routine gerrymandering with the city's electoral boundaries, incurring as a result a reproof from the courts. But last Thursday morning, the shame hanging over the city was the humiliating defeat the previous evening of the city's most prosperous baseball team, the New York Yankees. In the process, the Yankees also lost the best-of-seven competition between North American baseball teams quaintly known as the "World Series". Last week's defeat was all the more galling because the Yankees were soundly beaten by the Los Angeles Dodgers, within living memory resident in Brooklyn and much resented for their defection. This gloom is yet another proof that something must be done to reform spectator sports in which the object is to hit a ball with some solid object, in baseball called a "bat"

At least to a first approximation, the interaction of a baseball and a bat is a soluble two-body problem. The bat in baseball is a simple object, cylindrically symmetrical about an axis, while the complication arising because some ball-throwers (called "pitchers") claim to be able to throw "curve-balls" is irrelevant to last week's disasters because both teams appear to have been incapable of hitting them. Moreover, since baseball officials have taken to measuring the speed with which individual baseballs are delivered, there is a wealth of empirical data on which a proper mechanics of baseball might be founded. Speeds of up to 40 metres per second are recorded.

The difficulty of baseball is, first, that of hitting the ball and, second, that of knowing where it will go when hit: good players appear to be able to hit one fair ball in three, but usually even the best players appear at a loss to know whether the ball will shoot high in the air (in which case it may be caught and they will be dismissed), vertically downwards into the ground or upwards and backwards, into the crowd. Only occasionally, perhaps half a dozen times in several hours, does the ball perform as every batter hopes, carrying over the boundary fence for a home run. Thus, it appears, baseball has become an elaborate game of chance. In this year's World Series, there seems to have been very little to choose between the batting performance of the two teams. Part of the reason why the Yankees lost is that they were not as skilled at catching and throwing the ball as were the Dodgers. It is now a matter of great importance to devise some way of ridding baseball of the luck on which it now depends, and which is a simple consequence of the circular cross-section of the baseball bat. Is there a place in baseball for the cricket bat?

Even New Yorkers will, however, agree that the most serious cause of the Yankees' defeat was the evil chance that attended one of the crucial decisions by the team's manager, Mr Robert Lemon. The issue is complicated by the requirements of this year's rules for the World Series that the pitcher, the man who throws the ball for his team, should also take his turn with the bat. At a point half-way through last Wednesday's game, Mr Lemon exercised his right to replace his successful pitcher due to bat with somebody reputed to be more skilled at hitting the ball, but who promptly failed to do so. Yet if the gamble had succeeded, the Yankees would have gained three runs and the Dodgers would have been too demoralized to sustain the struggle. What will happen now to Mr Lemon, who works for an owner so hottempered that he had to watch Wednesday's game with his hand in a cast after a fist-fight in a Los Angeles elevator, remains to be seen. Wisely, he has been keeping his own counsel. But is it not demeaning, and intolerable, that grown men's careers and the temper of a great city should be determined by the apparently random trajectories produced by trying to hit a baseball with a cylindrically symmetrical bat?

# Back to basics for high-energy physics

# US panel's ritual defence of accelerator

Washington

The high-energy physics community in the United States is lifting only the littlest of fingers in defence of the proton-antiproton accelerator ISABELLE at the Brookhaven National Laboratory, Long Island. At a day-long meeting on Sunday, the influential High Energy Physics Advisory Committee accepted a subcommitee's recommendation that the accelerator should be completed only if there were a prior assurance of adequate support for research at the two other accelerator laboratories at Stanford, California, and Fermi National Accelerator Laboratory (Fermilab), Illinois.

ISABELLE may thus turn out to be the most conspicuous casualty of the new financial restraint. The physical infrastructure of the machine, a tunnel 2.5 miles in circumference, is 95 per cent complete. But something like a further \$500 million would have to be spent on magnets, vacuum systems and radio-frequency accelerating cavities if the accelerator was to be finished by 1990.

If the project is abandoned, some 400 technical people at the Brookhaven Laboratory will be without jobs. There is even the gloomy possibility that, without its chief task, the survival of the laboratory itself will be in jeopardy.

The subcommittee report, the sole item

on Sunday's agenda, had been prepared in less than three months by a group under Dr George Trilling of the University of California, Berkeley. The panel will go on to produce a more measured statement in January of the benefits that may derive from particle accelerators based on novel principles such as those being developed at Stanford and Cornell universities. This

by the Department of Energy's need of an opinion from the high-energy physics community in advance of this week's crucial decisions within the Administration on how the latest 12 per cent budget cuts will be distributed.

week's interim report was made necessary

Given the conflicting interests of its members, the panel's chief conclusion is understandably delphic. It "strongly recommends" that ISABELLE should be completed, goes on to argue that the total cost of high-energy physics to the Department of Energy would then be \$440 million a year and remarks that if this support is not forthcoming, the ISABELLE project cannot be continued.

At present, high-energy physics is

operating on a budget of \$325 million a year, at which level the principal accelerators cannot be operated full time for lack of funds with which to pay the electricity bills.

There is every sign that high-energy physics has reached a turning point in the United States. Three distinguishable constituencies have emerged — the operators of the accelerators at Fermilab and Stanford, who wish to see their equipment fully used, the adherents of ISABELLE, who argue that it is an essential tool for the 1990s, and the general university users of accelerators, who need more immediate access to existing machines but who recognize that without ISABELLE they will have even fewer experimental opportunities ten years from now. The interim report spells out the conditions that must be satisfied before funds are spent on the completion of ISABELLE:

- Full utilization of existing accelerators.
- Completion of the Tevatron 1 accelerator upgrade for colliding 1,000 GeV protons and antiprotons based on existing Fermilab accelerators.
- A start on work on the Tevatron II

project, intended as the chief fixed-target accelerator for the 1980s.

- Development of superconducting radio-frequency cavities (at Cornell University).
- Development of novel accelerator designs.

Much of Sunday's meeting was occupied with the cost of this minimal programme, eventually fixed at \$395 million a year: if ISABELLE were to be completed, the total high-energy physics budget of \$440 million a year would include an average of \$80 million a year for the construction of the machine. If, however, ISABELLE is abandoned, the committee argued, it would be necessary to spend an extra \$35 million on research and development on new accelerator technology.

The committee's optimism that its "minimal" programme may be funded derives from the agreement in 1979 between the Department of Energy and the Office of Management and Budget that high-energy physics could count on a budget of \$300 million a year, adjusted for inflation. Several members argued that even with the completion of ISABELLE,

#### Top men resign in CNRS crisis

The two heads of the largest research agency in France — the Centre National de la Recherche Scientifique (CNRS) — fell last week in a self-delivered coup de grace.

On Wednesday, M. Jacques Ducuing, the director-general of CNRS, handed in his resignation to the minister for research and technology, M. Jean-Pierre Chevènement. Shortly after, the president of CNRS, Professor Charles Thibault — who worked in tandem with Ducuing — resigned also. He was followed by three of the six scientific members of the CNRS council, and the other three, including Louis Néel, a Nobel laureate representing the Académie de France, are likely to resign soon. (Néel, however, awaits the recommendation of the Académie.)

So what was the fuss? Chevenement was planning to wait until early next year before making any major changes at CNRS (and elsewhere) by which time he would have tested the water with the national colloquium on science and technology. The unions were unhappy with the CNRS directorate and had called for their resignation; but there was no sign of any movement yet.

Then, on Tuesday, after a long Socialist Party congress in which the party appeared to move to the left and chided the government for failing to confront the establishment more firmly, Chevènement decided he wanted to sack M. Christian Morrisson who was appointed director of social sciences at CNRS in April (beforé the general election).

Morrisson, it seems, was taking CNRS

social science in completely the opposite direction from Chevenement's own interests. The minister would like to expand social sciences in France, but in the direction of immediate public concern—such as unemployment, or the changes implied by new technologies. Morrisson's interests were more academic.

So Chevenement called Ducuing and asked him if at the council meeting due the following day he would propose that Morrisson be replaced by someone more sympathetic — a M. Maurice Godelier, professor of anthropology at the Ecole des Hautes Etudes. Ducuing asked for more time to consult his colleagues but was refused. He resigned, and the other resignations followed, on the principle that the minister's insistence was an interference with scientists' responsibilities.

Chevenement, however, did not seem too disturbed by the events, despite the cries of some that the resignations would throw out of joint his whole plan for the reorganization of science and technology in France. At a press conference on Wednesday he asked journalists why they were so excited about the affair, pointing out that he had only proposed one change whereas in America the whole top administration was turned over at a change of government.

The minister now has a clear field on which to place his men, well before he had expected the opportunity. He is likely to be quick to make new appointments, though they must be approved by the council of ministers.

Robert Walgate

their budget is in real terms not very different from what was agreed three years ago. Others say that little purpose is served in reminding one Administration of promises made by its predecessor.

One of the ironies of ISABELLE is that the problems of magnet design which have delayed the project by about four years appear in the past few weeks to have been resolved. If the Administration practises what it has been preaching the only remaining hope for the accelerators is that Congress may choose to appropriate funds for the project against the Administration's wishes

#### High-energy physics

#### LEP approved

While American physicists agonize over the future of a new accelerator (see above), twelve European nations last week agreed in principle to the construction of LEP, a 27-km circumference machine to collide electrons with positrons at energies up to 50 GeV per beam — enough to create the long-sought neutral intermediate vector boson.

The twelve nations are the members of CERN, the European centre for research on nuclear physics at Geneva where LEP will be constructed. Three members (the Netherlands, Sweden and Norway) have given approval subject to parliamentary approval at home.

The principal questions still hanging over LEP concern the precise annual budget at which it will be built — which affects how rapidly it might be brought into service — and environmental opposition in the French and Swiss territory under which the LEP tunnel must be bored.

If all goes well the budget will be decided at the December meeting of CERN Council. (On CERN's own plans, it would be about 630 million Swiss francs a year — £182 million — enough to have LEP in action by early 1987.)

But environmental approval is more unpredictable. At present, CERN is restricted from building even a reconnaissance gallery. The gallery is needed to permit inspection of the geologically critical boundary between the sandstone floor of the Geneva valley and the limestone Jura Mountains to the north (under which the LEP tunnel must pass), but a Lyons court ruled that CERN had no valid licence for the work. CERN has now guaranteed that the accelerator will not be built until and unless the appropriate local French and Swiss procedures for approving large constructions are completed successfully.

Such approval is yet to come — for the French and Swiss accession to LEP at the level of CERN Council was made at ministry level, and is subject to local approval. However, CERN staff are confident that the environmental "dangers" of LEP — for example that it might affect the water table — have been wildly exaggerated, and that local approval will be granted.

US research support

#### **Academy exhales**

Washington

Dr Frank Press's first essay as a constituency lobbyist since his election as president of the National Academy of Sciences, his colloquium on the latest budget proposals on Monday and Tuesday last week, was a tactical success. Its most tangible product, a document labelled "consensus statement", drafted in a closed session on the second day, is a nice amalgam of moderate belligerence and sympathy for the Administration's economic problems.

The colloquium itself was the first response of what the labour unions might call organized science to the decision in September that all federal agencies except the Department of Defense must reduce their discretionary expenditure by 12 per cent. (NASA, for the current financial year, is let off lightly at 6 per cent but has been told that 1983 will be worse). Discretionary expenditure is that not mandated by explicit provisions in legislation.

The consensus statement acknowledges that economic problems "have eroded research and development", but says that the new budget proposals will do "irreparable damage" unless long-term research is protected, if necessary at the expense of "development and demonstration". The document urges the Administration to assume responsibility for supporting scientific research, but asks for a formal review of the machinery by which this is done.

Before the definition of consensus preoccupied the colloquium, diversity was rampant. One speaker was so alarmed by the threatened 12 per cent reduction as to fear a return to pre-Sputnik days. Another warned his academic colleagues not to expect too much from industry, whose support now accounts for 3 per cent of university budgets. Industrial grants would have to increase threefold to make good the damage done by the 12 per cent cut.

The colloquium also broke new ground by giving currency to the word "prioritization" — deciding what research should be given first claim on limited funds. This notion is in sharp contrast with earlier declarations of faith in a plurality of sources of funds.

The statement argues that the abruptness of the new cuts will be especially damaging. This is well illustrated by the plight of the National Science Foundation, none of whose expenditure is mandated by Congress, but which finds itself committed to the US Navy for support of the Antarctic research programme as well as to several national laboratories. It has become known in the past few days that these commitments may mean that the softer, grantmaking parts of the foundation may find their budgets cut by up to 18 per cent, especially if spending on social science,

education and international relations (cut severely in March) is now protected.

Among the hundred participants the two principal government representatives appear to have left contrasting impressions on their audience. Dr J. Khaduri, one of the hard men from the Office of Management and Budget, preached economic realism and told his listeners that they would lose more from continued inflation

Press, moderately belligerent; Keyworth, inscrutable

than from the government's emergency budget. In the meantime, he declared, there is bound to be hardship. But at least there is also a chance that scientific enterprise could be growing again on the basis of a "new equilibrium" and with the help of dollars whose value remained constant from one year to the next. It is unfortunate that the Secretary of the Treasury, Mr Donald Regan, should have had to admit a few days later that the federal budget would probably not be balanced by 1984.

Dr George Keyworth's declaration seems to have been harder to interpret. The science community is not yet sure whether to regard him as a friend at court or as the Administration's lightning rod. Dr Keyworth himself is probably not yet sure. Last week, however, he left at least some of his audience with the impression that he believes the consequences of the emergency budget will be less serious than now seems likely. Does he know something, or is he simply being well mannered?

#### European space policy

#### New satellites due

Europe's activities in space received new impetus with the announcement last week that the United Kingdom is willing to make its contribution to the Large Telecommunications Satellite (LSAT-1), and with the decisions made at a European Space Agency (ESA) council meeting to recommend three projects to member nations for further development. Provided the member states do not refuse to fund them, the three projects - the Earth Resources Satellite (ERS-1), the Ariane 4 launcher and the Spacelab "follow-on" spacecraft - will begin their next development stages in about three months' time. Other issues of great concern to the members of ESA - particularly collaboration with the United States and the ten-year plan of ESA's director, Erik Quistgaard (Nature 290, p.536) - have been deferred until the next council meeting in December.

The Minister for Information Technology at the British Department of Industry, Mr Kenneth Baker, announced last Friday that the United Kingdom was willing to provide its 34 per cent share towards the cost of LSAT-1 (which would amount to about £77 million over the next ten years). The project will only proceed once other interested ESA members, particularly Italy, the Netherlands and Canada, have decided to fund it.

The concern of the United Kingdom has been that the balance of responsibilities for the specifications, management and marketing of the satellite, both before and after its expected launch on Ariane early in 1986, should be shifted from ESA to industry. The satellite will carry four groups of payloads, two of them primarily commercial, the others more experimental. The former are to be funded mainly by Britain and Italy, and are intended to provide efficient communications for businesses and facilities for high-powered direct broadcasting of television. The two more experimental payloads, involving Italy and Belgium, will function in the millimetre (20-30 GHz) waveband, and are intended to investigate signal propagation characteristics at these frequencies. Once the usefulness of LSAT-1 has been adequately demonstrated, further satellites of this type may be developed on a commercial basis and - to this end - the satellite has been designed to be launched by either Ariane or the space shuttle.

The decisions made at last week's ESA council meeting have increased the chances for launches of the Earth Resources Satellite, Ariane 4 and the successor to Spacelab in 1986 or thereabouts.

The successor to Spacelab will involve the development of increased electrical power and mission duration within the present Spacelab configuration. ESA's recommendation, if funded by member countries, will initiate the construction of this craft. Moreover, there will begin a study into the development of a pallet that would be launched from the shuttle to be retrieved from low Earth orbit later.

Ariane 4 is, to some extent, ESA's answer to the space shuttle, in that current models of Ariane cannot launch the large payloads that may be required over the period 1985-95. Modifications to the first stage, allowing an increased fuel volume and the addition of liquid fuelled boosters, will increase Ariane's maximum payload capacity to 4,300 kg (as opposed to Ariane 3's limit of 2,460 kg). It is intended that Ariane 4 will not only launch single large satellites such as Intelsat 6 but also provide an improved dual launch facility.

The oceanographic remote sensing satellite ERS-1 is now set for the second stage of its feasibility study, involving a detailed design and costing. Experiments already earmarked for the satellite will investigate the wind field and ocean wave

heights. An announcement of opportunity has also been issued for prospective experimenters to fill the remaining 50 kg of payload capacity. The final decisions on the mission's design and instrumentation will be taken in 1983. One problem still to be decided upon concerns the distribution of data from ERS-1, particularly the degree to which this is centralized.

Philip Campbell

#### Enrironment research council

#### Rothschild persists

The Rothschild customer/contractor principle, whereby British government departments (the customers) commission research in the research councils (the contractors) is still alive in environmental research, despite its demise in medical research and modification in agricultural research earlier this year. Its survival seems to be largely due to Sir Hermann Bondi, a well-known advocate of the principle, who has been chairman of the Natural Environment Research Council (NERC) for the past year.

Sir Hermann believes that the principle will work well, but only if NERC is careful to accept those contracts which will benefit its research as well as satisfying the customer. He also acknowledges the difficulties inherent in multi-customer contracts which can put a project at risk if one customer decides to withdraw support.

One such casualty is the £5 million Land Geological Survey of Great Britain which was threatened when the Department of the Environment, largest of the three customers, decided to cut its contribution for 1981-82 to two-thirds of its level in 1980-81 and to support only tactical research directed mainly at resource planning.

It plans a further cut in 1982-83. The result has been a substantial reduction in the amount of strategic and long-term research which is mainly geared to detailed geological mapping.

Despite these problems, however, Sir Hermann remains optimistic about the work of NERC. When introducing its annual report last week (HMSO, £4.00), he said that he had had a "marvellous time" during his first year as chairman. Although a slightly reduced budget has diminished the vigour with which the council can pursue some projects, he says he is impressed with the quality of the research it supports and sees no danger of stagnation.

During 1980-81, the year covered by the annual report, £26.1 million of the council's £72.9 million budget was earned from contracts, the remainder coming from the Department of Education and Science through the science vote. Support for universities, however, decreased slightly, with £75,000 less spent on new research grants than in the previous year (the council currently awards about £3 million of new research grants a year).

**Judy Redfearn** 

#### Hoechst in Boston

#### Contract cleared

Washington

Deft collaboration between the US General Accounting Office (GAO) and Congressman Albert Gore has now forced into the open the controversial agreement between Massachusetts General Hospital and Hoechst AG, the Frankfurt-based chemicals company. Earlier this year, representatives of the hospital declined to hand over their agreement with Hoechst to a congressional subcommittee of which Mr Gore is the chairman, on the grounds of commercial confidentiality. Under the agreement, Hoechst will support a new department of molecular biology at the hospital, spending more than \$50 million in the coming decade. In return, Hoechst will have the first refusal on an exclusive licence to exploit any patents generated by the laboratory during the period of its financial support.

The intervention of GAO, prompted by Congressman Gore, was based on the possibility of a conflict between the hospital's agreement with Hoechst and the requirements of the 1980 amendments of the patent legislation which, among other things, gave non-profit making institutions such as the hospital the right to first refusal of patent rights arising from federally supported research. The provisions of the new patent legislation came into force on 1 July this year, two months after the hospital's agreement with the company.

Evidently, the new agreement between Hoechst and the hospital has been drafted with the new legislation in mind. GAO says, in a letter to Mr Gore, that it should be possible for the hospital to keep separate the research funded by Hoechst and that funded by federal agencies, the National Institutes of Health (NIH) in particular. As things are, the hospital's research programme is supported to the tune of \$30 million a year by grants from NIH.

Difficulties will arise, according to GAO, only when there is doubt over whether a patent exploited by Hoechst has been supported exclusively by funds provided by the company, or where patents arising from jointly funded projects would be dealt with differently under the agreements between the hospital and Hoechst and NIH respectively. In all the circumstances, both the hospital and the company are likely to lean over backwards to avoid complications of this kind. Even so, when making public the terms of the contract on 16 October, Mr Gore uttered dark threats about the necessity that US institutions made strong with public funds should assist American and not foreign industry.

The details of the contract now published are unlikely to offend academic susceptibilities. Hoechst's support of the new molecular biology laboratory is defined by a programme of payments that will include the best part of \$18 million for

laboratory accommodation and equipment as well as \$50 million over ten years for running costs. Both sums are indexed against inflation, while the hospital administration will be allowed to charge an overhead percentage (within the \$50 million) equal to that agreed from time to time with NIH.

Under the agreement, the hospital is required to patent all inventions arising from sponsored work, but at Hoechst's expense. The company will be automatically entitled to an exclusive licence for exploitation, but the hospital will be able to take back the rights of exploitation if the company delays for more than three years: the agreement specifies that the director of the new department of molecular biology should be Dr Howard Goodman, who is already in post. One of the potentially contentious points in the agreement is that senior appointments be decided "after consultation with the company". The agreement also requires that those appointed should be "as appropriate" recommended for tenured appointments at Harvard Medical School.

On publication, the agreement requires that the company should be sent a copy of any proposed publication 30 days before this is sent off for publication, during which period the company will decide whether patentable discoveries are involved: all those employed at the department will be required to sign service agreements declaring that the hospital authorities will be notified of any possibly patentable discoveries. Collaboration with others is permitted, provided that Hoechst's exclusive patent rights are not prejudiced. Consultancy for other companies and organizations is permitted so long as there is full disclosure and discussion with the director of the department.

The agreement also defines the way in which the proceeds from patent exploitation will be shared between the inventors, their department and the hospital at large. The agreement says that royalty percentages negotiated should ordinarily be half those appropriate to commercial agreements, and that royalty income should be deductable from the annual payments to which the company is committed.

The agreement now published is very similar to the outline account of it given to the Gore committee earlier in the year, so it is not obvious why the hospital withheld it from the committee.

#### **SERC** director looks to the future

Britain must collaborate with its European neighbours if it is to have a stake in building major new research facilities in the future, according to Professor John Kingman who succeeded Sir Geoffrey Allen as chairman of the Science and Engineering Research Council (SERC) on 1 October. Precisely how big and costly a facility will be before international collaboration becomes worth while will depend on SERC's future resources and on the needs of potential collaborators. But if SERC was embarking now on some of the major facilities it agreed in the mid-1970s then international collaboration would almost certainly make sense, according to Kingman.

Indeed, the council is already looking for European partners to help with the construction of the spallation neutron source at the Rutherford Laboratory which, at an estimated cost of £15 million, is due to come on line during 1984. One possible collaborator is Germany which has considered building a similar facility of its own. But the council has also held discussions with other countries which may wish to use the facility.

SERC's difficulties over building major facilities began in the late 1970s when its budget failed to keep up with inflation, forcing it to lengthen construction times for major facilities and leading to an inefficient use of resources. Worst affected has been the nuclear structure facility at the Daresbury Laboratory which was originally due to come on line in 1978. Technical difficulties and a shortage of money at the right time have delayed its commissioning

until March 1982, although the capital cost (£13.5 million at 1980 prices) has kept roughly in line with inflation. The synchrotron radiation facility also at Daresbury, which was commissioned last June eighteen months behind schedule, has suffered a similar, but less acute problem.

Despite a static budget, however, SERC has had some recent successes. Kingman is particularly impressed with the work of the council's three directorates in encouraging collaboration on engineering research between academics and industry. The council set up its fourth directorate in biotechnology last week (see this page) but Kingman is doubtful that it can afford to set up a fifth in microelectronics unless it can transfer responsibility for those in marine and polymer engineering to industry in general or the Department of Industry in particular.

One of Kingman's major problems will be how to maintain the quality of science in British universities which are suffering an unprecedented cutback in income. Although he is sceptical of government promises to maintain the real value of the science vote, he says that he is determined to maintain spending on research grants and studentships at least at its present level. That could mean convincing the Advisory Board for the Research Councils, which divides the science vote between the five research councils, that SERC should have a larger slice of the cake. It will also mean maintaining numbers in the face of overall cuts in research studentships already made by the Department of Education and Judy Redfearn Science.

#### UK biotechnology

#### Still striving

The British Science and Engineering Research Council (SERC) last week launched a new directorate to foster collaboration in biotechnology between academics and industry and to forestall any brain drain of British biotechnologists to greener pastures abroad. The new biotechnology directorate is partly a response to a major study, chaired by Dr Alfred Spinks, which recommended nearly two years ago that Britain must act swiftly if it is not to lose out on the commercial development of biotechnology. Contrary to appearances, however, SERC has not been tardy in its response, according to Dr Geoffrey Potter. who will lead the new directorate. SERC's specialist panel on biotechnology spent the past year working out precisely what to do.

The biotechnology directorate will perform a function similar to the existing SERC directorates in polymer and marine engineering except that it will report to both the science board and the engineering board, reflecting the broad spectrum of research that biotechnology encompasses. One of its most difficult tasks, according to Dr Potter, will be to motivate process engineers, notoriously more reluctant than microbiologists to seize opportunities in biotechnology.

The directorate's funds will only be modest, £1 million this year rising to £2.4 million by 1984-85. The extra money will come from the Advisory Board for the Research Councils and from economies in SERC's other activities.

Most of the money will be spent on fostering collaboration through schemes already used by SERC to get industry involved in research in universities. These include the teaching company scheme and Cooperative Awards in Science and Engineering (CASE), both of which support postgraduate students on research projects relevant to collaborating companies, and the cooperative grant scheme whereby SERC and collaborating companies chip in to the cost of research projects in university laboratories.

SERC is particularly keen to encourage collaboration on fermentation, enzyme and immobilized cell technology, separation and concentration technology, product processing and recombinant DNA research. The directorate is to work closely with the Department of Industry which may take over funding of projects approaching the development stage, and with the Agricultural Research Council and Medical Research Council, both of which also support biotechnology.

One of the directorate's aims, according to Dr Potter, is to create sufficient jobs to dissuade British biotechnologists from taking posts in industry and universities abroad and even to persuade those who have already left to return. Dr Potter's concern about a possible brain drain is

shared by the members of a Royal Society working party, chaired by Professor W.D.P. Stewart, which will shortly publish a report on biotechnology and education.

The working party estimates that over the next ten years Britain will need 1,000 extra graduates and 4,000 technicians trained in biotechnology. It does not, however, favour new undergraduate courses specifically in biotechnology; training should insted be based on existing undergraduate courses in biology and chemical engineering followed by more specialized postgraduate courses.

The working party also supports a recommendation originally made in the Spinks report that the University Grants Committee should create 20 new lectureships in selected universities. That request, together with many of the Spinks recommendations, received short shrift from the government, which said in a White Paper earlier this year that the development of biotechnology in Britain should depend on market forces rather than government intervention.

Judy Redfearn

#### **Hungarian protests**

The use of psychiatric methods to treat political dissent has reappeared in Hungary for the first time in more than a decade, with the confinement in a Budapest mental hospital of Dr Tibor Pakh, a 57-year-old lawyer and activist from 1956. Dr Pakh's hospitalization evoked a sharp letter of protest from more than 50 Hungarian intellectuals and scholars.

Since the rise of Solidarity, Dr Path has issued a number of open letters supporting the Polish liberalization and censuring the Hungarian authorities for echoing Moscow's condemnations of it.

On 4 October 1981, Dr Pakh attempted to travel to Poland. He was stopped at the Hungarian frontier, his passport and personal papers were confiscated, and he was forced to return to Budapest. On 6 October, when his protest to the Procurator General's office failed to obtain satisfaction, he began a protest fast in the University Church in Budapest. Three days later, he was forcibly conveyed to hospital, and given intravenous feeding and heavy doses of psychotropic drugs including haloperidol, one of the drugs used in similar cases in the Soviet Union.

The group of intellectuals who signed the protest letter maintained a constant stream of visitors to the hospital, demanding to see Dr Pakh and also forwarded their protest to Solidarity, who published it in their uncensored bulletin *Niezaleznosc*. The protesters apparently made their point, and on 26 October, Dr Pakh was released, ostensibly on "readjustment leave".

Vera Rich

#### Interferon

#### Gamma winners

Molecular biologists at the Californian biotechnology company of Genentech have won the race to clone a sequence of DNA corresponding to  $\gamma$  interferon, the least understood member of the family of proteins which may yet find a place in the therapy of cancer and viral diseases. At the same time Molloy Laboratories, a subsidiary of Revlon, have been contracted by the US National Cancer Institute (NCI) to purify sufficient  $\gamma$  interferon from natural sources for initial clinical trials.

The Genentech results, briefly presented by Dr David Goeddel at the Second Annual International Congress for Interferon Research in San Francisco, not only establish the sequence of y interferon but also show that bacteria, yeast or mammalian cells are able to produce y interferon when supplied with the corresponding sequence of DNA.

The starting material for both Genentech and Molloy was human lymphocytes, prime producers of y interferon. From them Genentech isolated a mixture of messenger RNA molecules, produced the complementary DNA molecules, and transplanted them into cells of the bacterium Escherichia coli. Bacteria were then isolated which were producing the antiviral activity of interferon but with the instability towards acid that distinguishes y interferon from the  $\alpha$  and  $\beta$  varieties. Finally the DNA responsible for that activity was sequenced and shown to be about the same length as that of a interferons but with an unrelated sequence.

Human lymphocytes are also the starting material for the y interferon that Molloy, in return for \$270,000 from the NCI, are to produce by traditional methods of purification from normal white blood cells obtained as a by-product of blood transfusion. Their aim is to produce five billion units of y interferon, enough for up to 1,000 human doses, by the end of September 1982.

It is a matter of speculation whether the Genentech and Molloy materials will be equivalent. A lot depends on whether there is a single  $\gamma$  interferon or whether, like  $\alpha$  interferon, it is a family of related molecules. Genentech has no evidence of more than one species but if they do exist they are likely soon to be discovered either by the Genentech scientists or by those whom they beat to the first sequence, including Dr Charles Weissmann on behalf of Biogen, Dr Jan Vilcek of New York University Medical Center and Dr Leroy Hood of the Californian Institute of Technology.

The hope of all concerned is that y interferon will be of greater value than its stablemates in the therapy of cancer. The hope stems from the fact that antitumour effects of interferon are thought to work through the immune system and that y interferon is produced by and has effects on cells of that system. Reasonably large clinical trials of  $\alpha$  and  $\beta$  interferon against cancer and viral diseases are currently under way using material purified from cells. It will be some time before their value is clear and even longer before it is known if  $\gamma$  inteferon is more effective.

Peter Newmark

#### Royal Botanical Gardens

#### Look to the margins

This week sees a new man in charge of the Royal Botanical Gardens at Kew in London — Professor Arthur Bell, a biochemist, formerly head of the department of plant sciences at King's College. And it could mean a very different approach for an institution with a 140-year history of traditional botany behind it.

The Royal Botanical Gardens today include Kew together with a 600-acre estate at Wakehurst Place in Sussex, and are run as a department of the Ministry of Agriculture, Fisheries and Food with a scientific staff of almost 500. The emphasis is still very much on the traditional pursuits

Bell in situ at Kew

of collecting wild plant species (Kew boasts the world's largest herbarium) and taxonomy. Kew's new director, however, brings with him an enthusiasm for plant breeding not seen there before. And Professor Bell has a clear goal in view — to change the pattern of agriculture in the Third World.

At present just thirty plant species provide eighty per cent of the world's food supply. Many of these basic food crops are now grown in arid conditions far removed from those in which their free-growing ancestors used to thrive. Professor Bell's contention is that there are many indigenous crops used only as animal fodder, or unpalatable because of the presence of toxins, which would give better yields than today's food crops if suitable variants were selected. Therefore much of Kew's effort will centre on isolating variants of these so-called "marginal" crops which do not produce toxins, but which still grow well in arid climates. In this way perhaps Kew will again become the important source of new crops that it once Charles Wenz was.

#### CORRESPONDENCE

#### **Brazilian funds**

SIR — I would like to correct some of the statements made by Mr Bazin in his article "Brazilian research funds: Sliding backwards" (Nature 6 August, p.489).

First, the Brazilian government has a clear and explicit policy statement regarding science and technology. This was published in the form of the 3rd Basic Plan for Scientific and Technological Development (1980–85) and stated in the 3rd National Development Plan.

Second, the Brazilian government, in harmony with the high priority given to science, has maintained a steady and growing support for scientific and technological activities. Financial resources allocated to science and technology in the federal budget are shown in Table 1.

Table 1 Federal support for science and technology

	Science and technology budget	% Of
Year	(US\$ million)	federal budget
1980	352	2.1%
1981	435	2.3%
1982	909*	3.6%

\*Proposal now in discussion in Congress.

Third, the National Research Council (CNPq) which is the central coordinating agency for science and technology in Brazil, has had and has now an important role to maintain and reinforce this growing public

Table 2 CNPq's budget

Year	Total budget (US\$ million)	% Allocated for grants and scholarships
1980	122	31.9%
1981	144	33.7%
1982	188*	38.0%
*Proposal		

support for research in the country. The data in Table 2 show that CNPq's budget, as well as the resources allocated for grants and scholarships, have outpaced inflation.

ERNO IVAN PAULINYI

CNPq, Brasilia, Brazil

MAURICE BAZIN REPLIES — When considering whether Brazil's research spending has kept pace with inflation it should be remembered that inflation in Brazil was over 80 per cent in 1980 and is now around 110 per cent.

#### Gold standard

SIR — The reexamination of the gold standard in the United States is motivated by more serious concerns than your article on the subject suggested (*Nature* 24 September, p.246). For, despite its faults, the gold standard performed an essential function for which no other arrangement has so far been able to substitute in a democracy. It provided an impartial mechanism which the general public accepted as justification for the monetary discipline necessary to prevent accelerating inflation.

From 1717, when Sir Isaac Newton established the official buying and selling prices of gold at 77/9d and 77/10½d per troy ounce, until the outbreak of the First World

War in 1914 (apart from a period around the Napoleonic Wars), a pound sterling was worth ¼ ounce of gold (within 1 per cent), and it was universally accepted that the Bank of England should maintain adequate reserves of gold to guarantee sterling's convertibility. Thus, when official gold reserves fell below a prudent level, the steps necessary to increase them, including in particular the raising of interest rates, were accepted by the public (and the parliamentary opposition) in preference to the abandonment of the gold standard.

By contrast, since the last link with gold was broken in 1971, there has been no economic "yardstick" which is publicly accepted as an objective measure of sound monetary policy, and periods of economic difficulty are blamed on the incumbent government rather than on our own behaviour. Politicians have inevitably tried to "buy" popularity, and as a result, in only ten years, sterling has been devalued by 75 per cent in real terms, at terrible economic and social cost to the United Kingdom. The United States is surprisingly close behind.

There is, in fact, a very great need to link currency to a real measure of value in a system of which the soundness and impartiality are beyond question and clear to both public and politicians. However, the standard should not be some "short-lived exotic radioactive isotope" as you suggest, but should be a range of the durable, essential, basic commodities on which all economic activity depends. The many far-reaching advantages of such a policy have been described by a number of economists over the past century, but the specification of a practical system is complicated by the need for commodity prices to respond to market forces; they cannot be fixed as was the price of gold. Nevertheless it would be possible to achieve the desired results by establishing a rule by which official buying and selling prices of specified commodities were adjusted automatically according to the levels of official reserves. Such a system has been widely endorsed by economists from across the political spectrum, one writing in 1958: "It can be only a question of time before man's reason and self-interest overcome his inertia and these proposals are accepted. When they are they will define the beginning of an era as surely as did the introduction of the gold standard, but without its fatal weakness"

Institutional resistance to change has so far prevented the adoption of such an innovation. But until we do, inflation will continue, with all its destructive consequences (and economics will continue to be as unscientific as physics would be without the ruler).

P.Q. COLLINS Imperial College of Science and Technology, London, UK

#### Lab animals

SIR — Your article on "Protection for laboratory animals" (Nature 17 September, p.173) offers an ineffectual solution to the problem of how to regulate the use of animals in research. Your suggestion of establishing a committee at each institution empowered to sanction proposed uses of laboratory animals seems like an attempt to eliminate regulation entirely. No research facility would refuse to sanction the use of animals for an experiment in which funding has been previously granted.

For regulation to be effective, it must be done by the agency responsible for funding.

Ignoring humane and philosophical considerations, the need for regulation is generated by the sheer numbers of research facilities in existence today. In order to prevent wasteful duplication of experiments, a coordinating agency must be empowered to determine the usefulness of a particular project. Since public monies are usually involved, the usefulness and more importantly the uniqueness of a study must be determined. Of course, a certain amount of replication of experimental results is necessary, but as there is virtually no communication between facilities, a parent agency must be involved to keep track of who is doing what.

We have a responsibility to the animal community, from which we have gained much information at the expense of much suffering, to use individuals as prudently as possible. Whether or not you believe an animal is capable of suffering in human terms is not important. It is a living entity, entitled to the life it was designed to lead.

Regulation of the use of animals in research experiments is essential to assure the proper use of public funds as well as the compliance with laws governing the humane treatment of the subjects. A governmental body, specifically the agency responsible for funding of research projects, must be responsible for the regulations.

Jackie Alan Giuliano Jet Propulsion Laboratory/California
Institute of Technology, Los Angeles, California, USA

SIR — I was pleased to see your editorial comment "Protection for laboratory animals?" (Nature 17 September, p.173). The Committee for the Reform of Animal Experimentation (CRAE), which is drawn from both houses of parliament and from the fields of science and medicine as well as animal welfare, has been seeking contact with members of the scientific community at all levels in order to find a "middle ground" where there can be agreement on many of the issues relating to the use of living animals for research. We would be very pleased to hear from those working with animals in laboratories if they have any points of view to express.

CRAE applauds your proposal for the setting up of ethical committees within research centres to act as a brake on undesirable experimentation. Such committees should be largely composed of researchers' peers but should also include what the courts describe as "the reasonable man", that is, responsible members of the local community.

The concept of ethical committees would fit very well with the Home Secretary's Advisory Committee proposals for a project licence as a requirement as well as a competence licence before a researcher could experiment.

One error in your editorial: although the 1876 Act requires experiments involving pain to be carried out under anaesthesia, such provision is the subject of exemption by the issue of Certificate "A" which permits the infliction of either severe or enduring pain, and it is only where an animal is found to be suffering severe and enduring pain that the experiment must be terminated.

#### NEWS AND VIEWS

# Integration of foreign genes into the mammalian germ line: genetic engineering enters a new era

from Brigid Hogan and Jeffrey Williams

THE application of recombinant DNA technology to mammalian cells is gradually yielding a rich harvest of cloned chromosomal fragments containing specific genes and their flanking sequences. Some of these cloned DNAs have been reintroduced into tissue culture cells where in many cases they are efficiently expressed. However, these experiments are of little value when it comes to identifying DNA sequences which control the temporal and tissue-specific expression of genes during embryonic development. To study these problems, a number of laboratories have injected cloned DNA into early mouse embryos and seen if the genes become stably integrated into the

It was hoped that the injected embryos would grow into adults, each carrying the same exogenous DNA inserted into different chromosomal sites in their eggs or sperm. Offspring of these individuals would then generate mouse substrains with the inserted DNA in all cells right from the start of development, allowing the effect on gene expression of such factors as neighbouring sequences, chromatin structure and DNA methylation to be assessed. The results of these experiments are now being reported in varying degrees of detail, and the consensus is that the bold approach has paid off, with the process of chromosomal integration being more efficient than people had dared imagine.

Support for the idea that cloned genomic DNA could be inserted into the germ line via the early embryo came from the work of Rudolf Jaenisch and his colleagues1-3 on the stable integration of exogenous Moloney leukaemia virus (M-MuLV). When 4-16 cell or blastocyst stage mouse embryos are infected with virus and then implanted into foster mothers, around 10-40 per cent per cent of the adults show active virus production in various tissues. Of these animals, a high proportion of the males can be shown to have M-MuLV DNA integrated into their germ line, since on mating with normal females they produce male offspring which transmit M-MuLV to 50 per cent of the next

generation (only males are studied, to avoid problems of in utero transmission of virus). The original virus-producing males developing from infected embryos show only a variable and declining transmission of M-MuLV. There are at least two reasons for this. First, the virus may only infect a few of the embryonic cells, giving rise to an adult in which the tissues are a 'mosaic' of cells with or without integrated virus. Second, spermatogenic cells carrying M-MuLV may be selected against in the mosaic testis as the animal ages. However, the second generation M-MuLV positive males carry viral sequences in all somatic cells, and transmit the DNA as a normal, dominant, gene to 50 per cent of their offspring. Using the technique of embryo infection, Jaenisch has generated thirteen different mouse substrains (Mov 1-13) carrying M-MuLV in specific sites. Study of these substrains has led to the exciting observation that integration of virus into different sites results in different temporal and tissue-specific patterns of viral

In Mov-1 mice, for example, virus production is first seen in the spleen soon after birth, while in Mov-13 mice virus activation occurs much earlier, in liver cells after only 16 days gestation. In other substrains, virus may never be activated during normal life. The pattern of M-MuLV expression is therefore influenced by the chromosomal site into which the virus is integrated.

The converse of this effect may be the influence of MuLV sequences on the expression of genes into or near which they are inserted. Recent studies from the Jackson Laboratory in Bar Harbor<sup>4</sup> have shown that the *dilute* coat-colour mutation in DBA-mice is linked to an endogenous MuLV sequence, and that spontaneous revertants from *dilute* to wild-type (d to  $d^+$ ) have also lost the viral sequence. It is therefore possible that the original d mutation, as well as other coat-colour mutations, are the result of provirus

Brigid Hogan and Jeffrey Williams are in the Imperial Cancer Research Fund, Mill Hill, London. integration into the genome.

In the experiments of Jaenisch and his colleagues described above, infection of preimplantation embryos led to mosaic adults composed of cells either lacking integrated virus or with virus integrated into different sites. However, more recent experiments5 have shown that if MuLV DNA cloned from Mov-3 animals is iniected into the cytoplasm of a fertilized egg. viral sequences can be found in all of the cells of the resulting adult. The integration does not appear to be direct, however, and is not into the Mov-3 site. Rather, it appears that the DNA is first transcribed and then reintegrated into a new stable site in the zygote genome. This method therefore provides a quicker way of studying the effect of chromosomal integration site on viral expression, and of inserting M-MuLV DNA into the germ line. Unfortunately, the answer to the problem of how to direct M-MuLV into a defined site remains elusive.

Laboratories attempting to insert functional chromosomal genes into the germ line have also tried injecting cloned DNA into the fertilized egg, although in these cases the DNA is actually injected into one of the two pronuclei before they have fused. The first reports to appear<sup>6,7</sup> showed that recombinant bacterial plasmids injected in this way were retained in some of the surviving animals in a high molecular weight form. The amount of DNA present was sufficient to suggest that most, if not all, of the cells contained multiple copies of the plasmid. Two obvious questions arise. Has the foreign DNA been recombined into the chromosomes and, if so, does the germ line contain integrated DNA? Both of these questions are now elegantly answered in experiments published in this issue of Nature (see p.92) by Constantini and Lacey of the Department of Zoology, Oxford. They injected a \( \lambda \) recombinant containing the adult rabbit  $\beta$ -globin gene and a  $\beta$ -like pseudogene  $\psi\beta2$  in a 19 kilobase chromosomal DNA fragment. Partial hepatectomies were performed on 24 of the mice, and total liver DNA screened for the

presence of rabbit  $\beta$ -globin genes by Southern blot hybridization. Nine of the mice contained rabbit  $\beta$ -globin genes in copy numbers varying in different individuals from one or two to up to twenty per cell although further experiments are now needed to establish whether the animals are mosaics, with some cells containing more copies and others none.

Four of the positive males were mated with normal females and DNA from the progeny screened for the presence of rabbit globin genes. Out of a total of eighteen progeny screened, six were found to contain rabbit globin sequences. This pattern of inheritance is consistent with a chromosomal location of the foreign DNA and, in a footnote to their paper, Constantini and Lacey describe the results of an in situ hybridization experiment showing that most, if not all, copies of the rabbit globin genes in one of their mice are located in the middle of one of the homologues of chromosome 1. The organization of the rabbit  $\beta$ -globin gene copies has been determined in a number of the mice by restriction mapping with various enzymes. Predominantly linear molecules of  $\lambda$  DNA were injected, but the integrated DNA contains the fusion fragment resulting from annealing of the  $\lambda$ cohesive ends. Consequently, the authors suggest that the input  $\lambda$  DNA is ligated to form high molecular weight concatemers and it is these tandem arrays which are then integrated into the chromosome. There is direct evidence that such a mechanism occurs for linear DNA injected into fertilized eggs of Xenopus laevis 8. Also Constantini and Lacey detect minor fragments which are transmitted to progeny mice, and which probably contain the junction between the terminal copies of the foreign DNA oligomers and host chromosomal DNA sequences.

What then of the questions posed at the outset? Are foreign genes which have become stably integrated into the mouse genome expressed, and do they display the correct temporal and tissue specific pattern of gene expression? A newly published study by Wagner and his colleagues at Ohio University, describing work done in collaboration with Hoppe at the Jackson Laboratory suggests that at least the first of these two important goals has been achieved9. A proportion of mice, derived from eggs which have been injected with a rabbit  $\beta$ -globin gene were found to contain a rabbit globin polypeptide in their erythrocytes, and this was also true of their progeny. Furthermore, a recent report in Science10, quotes preliminary evidence

obtained by Wagner which indicates that the rabbit globin polypeptide was produced only in red blood cell precursors and not in other tissues of the mouse. If this latter observation is confirmed, the way would seem to be open to determining those features of DNA structure important in controlling gene expression during development. Also, of course, if it has indeed been possible to insert a cloned gene sequence into the mammalian genome so that it functions correctly, the wider implications are enormous. Leaving aside the controversial question of gene therapy in humans, it seems certain that the genetic manipulation of agriculturally important animals will quickly follow, since, in cattle at least, the techniques of superovulation and reimplantation in foster mothers are now routine procedures.

#### Extraterrestrials where are they?

from Ben Zuckerman

IN THE MIDST of a sometimes depressing reality, many people take conscious or subconscious comfort in the assumption that we are but one of a myriad of advanced technical civilizations co-existing in our Milky Way galaxy. This view championed by articulate scientific and lay spokesmen — is bolstered by lavish science fiction movies, by reports of UFO encounters of the first, second, and third kinds, and by best selling books about artefacts left behind by so-called ancient astronauts

Included among the articulate scientific spokesmen is Carl Sagan of Cornell University, whose television programme and book Cosmos have brought astronomy into the homes of millions of Americans. Sagan, and some other well known scientists such as Philip Morrison (MIT) and Frank Drake (Cornell University), are considered to be members of the 'optimistic' school of thought on the question of extraterrestrial intelligence. They have argued that 100,000 or more technical civilizations, all of which have arisen independently, may currently exist in our Milky Way galaxy. If there are this many civilizations, then a typical one must exist for a million years or more.

How do the optimists arrive at this value for N, the number of technical civilizations in the Milky Way? Usually they rely on the 'Drake equation' which expresses N as a product of the various probabilities of the origin and evolution of life, intelligence, and technology. Sagan went through this exercise in Cosmos. He supplied his estimates for a long string of uncertain factors including, for example, the probability, P(life), that life will originate on an Earth-like planet and the probability that, having originated, it will then evolve to intelligence and technology. Since we really know very little about these probabilities, the optimists rely on the Copernican world view that we are not special. After all, most Europeans once believed that the Earth was located at the centre of the Solar System. After that was shown to be false, it was still commonly believed that the Sun was located at or near the centre of the Universe. As this now also seems most unlikely, the optimists argue, so should be the view that intelligent life is unique to the Earth given that there are hundreds of billions of stars in the Milky Way and most of them have been shining for at least five billion years.

This world view compels them to choose very large values for the probabilities mentioned above. For example, many (most?) scientists would regard P (life) as uncertain by a factor of at least a million. Yet Sagan, in Cosmos, purports to know P(life) to two significant figures. His choice of  $P(\text{life}) \sim 0.5$  is, ostensibly, the result of taking the arithmetical mean of unity, which he prefers, and zero which is preferred by some of the pessimists in this field. Of course, he would have obtained a very different value for N if he had instead set P(life) equal to zero, the geometrical mean of 1 and 0. This illustrates the kind of tricks that one can play with the Drake equation.

Until the past few years, there were very few scientists who would argue strongly against this Copernican philosophy. Ten years ago, when I first became seriously interested in this problem, I was sufficiently uncertain of the value of N that I attempted to search, with Patrick Palmer (University of Chicago), for radio signals from another civilization. We pointed the 300- and 140-foot telescopes of the US National Radio Astronomy Observatory towards approximately 670 nearby stars. Since then half a dozen similar attempts have been made by radio astronomers in the United States and Canada. None of these has been successful, unless someone is hiding something in their bottom drawer.

Radio beacons are, of course, but one of many ways that advanced technological societies could make their presence known to scientists here on Earth. The most obvious way would be for the extraterrestrials to send a manned or unmanned probe to our Solar System and, especially, to land one on Earth. That there is no real evidence that this has ever occurred has suggested to Michael Hart (Trinity University) and others that

advanced civilizations do not exist anywhere in our galaxy. We may well have the most advanced brains in the entire Milky Way.

At first glance it would seem to be a preposterous extrapolation to jump from the fact that we have not yet uncovered any evidence, either in deep space or in our Solar System, for superior extraterrestrial beings to the conclusion that they don't exist anywhere in the Milky Way. After all, our radio searches have been quite primitive and one can think of lots of reasons why another civilization might not want to go to the trouble and expense of sending complex probes between star systems.

This argument is reasonable if we are trying to understand why only a few civilizations might not want to send out interstellar spaceships. But what if there have been 100,000 or more civilizations, each of which must have existed, on the average, for a million years or more? Just as life and now, especially, intelligent life has transformed the face of the Earth so it might reasonably be expected that most of these 100,000 superior civilizations will have carried out deeds that, at present, we would regard as technological 'miracles'. Suggestions have included colonization and reengineering of the moons and planets of the home solar system to colonization and reengineering of the entire galaxy — all on time scales much less than 10 billion years.

Discussion of the many implications of these arguments filled an entire symposium whose proceedings, Extraterrestrials — Where Are They? are scheduled for publication by Pergamon Press in the autumn of 1981. Papers were presented by venerable pundits including, for example, Freeman Dyson (Institute for Advanced Study), Sebastian von Hoerner (National Radio Astronomy Observatory), and Ronald Bracewell (Stanford University) as well as by various comparative newcomers to this field.

Although many scientists find the arguments that N must be a very small number ( $\sim$  unity) quite compelling, few, if any, believe them to be so compelling that we should abandon searches for radio or infrared radiation from extraterrestrial beings. It is, therefore, ironical that Senator William Proxmire (Wisconsin) has entered these arguments into the Congressional Record of 30 July 1981 as part of his justification for prohibiting the use of federal funds during fiscal year 1982 for a modest radio search programme under consideration by NASA's Ames Research Center and the Jet Propulsion Laboratory. (He also felt that NASA wanted to search in the wrong place: "I have always thought that if [our best scientists] were going to look for intelligence, they ought to start right here in Washington. It is hard enough to find intelligent life right here. It may even be harder, I might say, than finding it outside

our Solar System.")

A few years ago Proxmire succeeded in deleting federal funds earmarked for a similar NASA search programme and gave NASA one of his Golden Fleece awards. Frank Drake, in return, gave Proxmire honorary membership of the Flat Earth Society but all to no avail. NASA has attempted to keep the programme alive, albeit at a minimal level, by using discretionary funds but the recent congressional action has stopped even that, at least for 1982.

This decision seems unfortunate for two reasons. First, there is considerable public interest in the search for intelligent life, judging, for example, from the response to Cosmos and the growing popularity of courses on "Life in the Universe" on college campuses. Second, and more generally, is it really in the best interests of American science for individual Congresspeople to fiddle with relatively minor items (about a million dollars a year) in the much larger budgets of major institutions such as NASA? Or, in the absence of a congressional vote of 'no confidence' in the NASA leadership, shouldn't the latter group, in conjunction with their scientists and engineers, be the ones who determine expenditures at the megadollar level?

# Histone gene organization: paradigm lost

from Larry Kedes and Rob Maxson

THE organizations of sea urchin and Drosophila melanogaster histone genes were shown, even before the era of gene splicing, to be remarkably similar: both are repeated in the hundreds and arranged in tandem units, each unit containing the intimately linked genes for five major histone proteins. While the differences between the sea urchin and the fruitfly histone gene topology hinted that the order and polarity of the genes within a species can be gently shuffled, the similarity between species so widely separated in evolutionary terms seemed to establish a paradigm for histone gene arrangement and lead to the confident expectation that similar arrangements would be found in intervening phyla.

However, a rash of recent reports of different patterns of histone gene organization in a number of different vertebrate species, including examples of scattered and often solitary genes, has dispatched classical notions about their fixed organization. The authors responsible for the new observations have been quick to point out the difference between the more familiar sea urchinfruitfly tandem organization and the vertebrate dispersed topology and to speculate on its significance. Human<sup>1-3</sup> mouse<sup>4</sup>, chicken<sup>5,6</sup> (see this issue of Nature, p.49) and toad7-9 genes have now been cloned. Not only are the genes differently arranged in comparison with the classical paradigm, but they seem scattered and separated by long stretches of non-histone DNA (for an extensive review see ref 10). While a few coding regions remain clustered, they are not at all arranged in clean-cut tandem repeats. Some coding regions are solitary and separated, by at least 10 to 20 kilobases, from their fellows. None seem to be an

identical copy of any other suggesting that dispersion allows, or at least associates with, evolutionary drift in gene sequence. Each coding region seems to be present only in tens per haploid genome. How close the histone gene members of this newly discovered diaspora are to one another in the genomic landscape has yet to be determined. An earlier report<sup>11</sup>, using *in situ* hybridization, suggests that the human genes may be landsmen: the locus seemed confined to the telomere of chromosome 7 but the genes are scattered over the entire distal third of the long arm.

Recent findings in our own laboratory suggest that the distinction between clustered and dispersed histone gene organization is not a strict interspecies difference. As pointed out by a number of workers, a gradual shift in expression occurs during early sea urchin development: the activity of the several hundredfold tandem clustered 'early' gene set is reduced in favour of the expression of a set of 'late' histone genes of much lower copy number. Some features of late sea urchin histone gene organization have now come to light with the cloning of several examples12. The late genes are scattered and shuffled not unlike those described for the vertebrate examples mentioned above. Genes coding for isoforms of the same histone exhibit extensive nucleotide sequence divergence. And to complicate matters, not all of the vertebrate genes follow the same model: histone genes in the newt12, Notophthalmus viridescens, share all the topological features of the sea urchin and fruitfly clustered arrangement except that each repeat unit is separated by a long

Larry Kedes and Rob Maxson are in the Department of Medicine at the Stanford Medical School.

stretch of satellite DNA.

Evolutionary models for the establishment of tandem gene clusters either from dispersed gene duplications, or by dispersal of gene elements from a tandemly amplified gene family, seem to be equally possible. Isolated dispersed members of tandem gene families14 have definitely been found among sea urchin and Drosophila histone gene families and among mouse alpha-globin genes<sup>15</sup>. Thus, mechanisms do exist that allow copies of gene regions to be banished to remote corners of the chromosomal countryside where they can diverge and possibly take on a new function or fall prev to new regulatory controls. Such a scenario may represent the mechanism that generated dispersed late sea urchin histone genes from the repetitive early cluster. Catastrophic deletion of an amplified cluster following speciation could account for the absence of tandemly repetitive histone genes among most vertebrates.

Equally convincing evidence may exist on the side of an explanation that holds that scattered organization predates the amplified cluster of genes. The yeast, Saccharomyces cerevisiae, has H3 and H4 genes head to head at one locus and H2B and H2A lying at another locus in the same posture<sup>16-18</sup>. Both loci are duplicated so only a dispersed organization exists in this protistan. Simple amplification by gene duplication and unequal crossing-over within one of the scattered clusters of histone genes may be the organizing principle that might generate a tandem cluster. There are those who correctly point out, however, that yeast is a simplified evolutionary descendant of more complex protista and that an examination of histone gene organization in algae or slime moulds, for example, might better establish the validity of this model.

These observations about apparently chaotic principles underlying the alternative arrangements of histone genes can hardly be considered as a "paradigm regained" but they underline the plasticity and organizational variability of functionally related regions of the eukaryotic genome and point out that we will continue to be surprised by further revelations about the degree of such diversity and mechanisms of generating it.

#### Poznan: Polish palaeohydrology presented

from Peter D. Moore

PALAEOHYDROLOGY is a topic which impinges upon many scientific disciplines. Physical geography, geomorphology, climatology and archaeology can all contribute to an understanding of why changes occurred in hydrological cycles in the past. Dry valleys, river palaeomeanders, the development of certain types of peat deposit, all bear witness to past conditions which may differ from those now found. To decipher such fossil geomorphological evidence and to reconstruct the hydrological conditions of past times could assist in the understanding of palaeoclimatic changes and help in seeing just how far reaching was the influence of prehistoric man upon his environment.

Poland has a long and distinguished history of research in this area and it is fitting that Poznan in Poland should form the centre for a recent conference on the palaeohydrology of the temperate zone.

L. Starkel (Krakow University) set out the complexities of this subject by showing how many varied factors have influenced the fluvial palaeoenvironment, including ice melt, sea level variation, tectonic effects and human impact. All of these have left their mark upon river patterns and sediments, thus making it difficult to evaluate the role of climatic changes. The late Pleistocene saw a change in river patterns from braided to meandering systems, which reflects lower fluvial activity following the final melting of ice and establishment of vegetation, but the trend has been interrupted on several occasions. Starkel claims that phases of increased fluvial activity recorded by such characteristics as increased grain size in fluvial deposits, more rebedded pollen and faster sedimentation rates, are synchronous over northern Europe. Periods of generally increased flood frequency occurred at 8,500-8,000, 6,800-5,800, 5,000-4,500 and 2,800-2,000 BP. All these, he claims, correspond to times of high lake levels and glacial advance, which supports the case for an overall climatic control. The increase in braiding pattern development in recent centuries, however, can be related to human activity.

It is very difficult, nevertheless, to demonstrate that any such effect is indeed purely climatic in origin. Very frequently, as discussed by K.J. Gregory (University of Southampton) and B. Frenzel (University of Stuttgart), one can detect evidence of increased human activity at precisely those times when palaeohydrological changes involving increased fluvial activity have

Petes D. Moore is in the Department of Plant Sciences, King's College, University of London. taken place. Forest clearance involves the reduction of transpiration rates in the vegetation and also lowers the interception of precipitation, thus permitting larger volumes of water to move through catchments into the rivers. Such evidence is often circumstantial, but its presence lays a considerable onus of proof upon those who would assert that purely climatic factors underlie the observed river changes.

Circumstantial evidence on one side can, of course, be countered by similarly based arguments on the other side. If widespread climatic changes can be demonstrated, which coincide with the fluvial palaeoevent, then this can support the climatic case. Beside evidence from glacial movements, the record supplied by pollen maps is becoming increasingly valuable, especially in the form presented by T. Webb (University of Providence, Rhode Island) who has developed transfer functions based upon modern pollen studies which allow him to translate fossil pollen maps into projected climatic ones. A similar piece of work hs been conducted by N.A. Khotinsky (Moscow University) who has constructed a series of Holocene vegetation maps for the USSR, based upon fossil pollen data, which permit palaeoclimatic interpretation. Data emerging from this work may have profound implications, as, for example, the discovery of the elm decline at about 5,000 BP far beyond the supposed geographic limits of Neolithic cultures in the USSR. The case for climate (or disease?) is strengthened.

Since synchroneity is the key to these arguments, dating of deposits relating to palaeohydrological and climatic events becomes critical. This problem is particularly well demonstrated by the river channel studies of S. Kozarski (University of Poznan) in the Warta valley of central Poland. Aerial photography and geomorphological mapping have revealed the scars left by the river during the course of its development. In one location to the south of Poznan, the river once bifurcated and the valley which no longer carries the Warta River has the scars associated with a braided pattern. The main river valley shows two series of palaeomeander scars, an outer series with a mean curvature radius of 200 m and an inner series with a mean radius of 123 m. These old channels have become blocked and form oxbow lakes filled with sand and peat as swamp and fen vegetation has colonized and ultimately obscured them. The sediments at the base of the channels, however, provide evidence which is useful in determining their date of origin and hence aids the reconstruction of the history

of the river's development. Palaeobotanical evidence (from macroremains, such as fruits and seeds, and from pollen) is also helpful and has been analysed by K. Tobolski (University of Poznan).

The outer, larger series of palaeomeanders contains botanical evidence of an origin during the closing phases of the last glaciation. The pollen spectra are herb dominated and the major tree components are birch and pine. The dwarf birch (Betula nana), juniper, Artemisia and Chenopodiaceae all provide evidence suggestive of open, park-tundra vegetation typifying late-glacial conditions. Precise location of the sediments within the lateglacial chronology is difficult, on the palaeobotanical evidence, and one wonders whether the argument about whether the basal deposits date from before or after the Bølling Interstadial can ever be resolved on this basis. The observed changes in sediment and pollen stratigraphy could so easily be a consequence of inwash from the steep sides of the channels, thus confusing the stratification of the deposits.

Radiocarbon dating has been attempted and figures in excess of 11,000 BP have been obtained for certain levels, but the sediments are calcareous, making the precise interpretation of such dates difficult. It is reasonable, however, to conclude that the development of the wider series of meanders (which replaced the braided system) occurred during the lateglacial. This could be accounted for by the reduced flow resulting from the completion of ice wastage, the development of a complete (and partly wooded) vegetation cover, and the possibility of reduced precipitation.

The inner series of meanders proved to be considerably younger. The pollen spectra of the basal sediments within these are tree dominated, with oak predominant. Available radio-carbon dates suggest that some of these younger palaeomeanders began forming around 4,000 years ago, and some later than this. The smaller radii suggest that more water was moving down the Warta, but whether this was a consequence of climatic changes or human deforestation is impossible to ascertain.

The enigma of man's role in the palaeohydrology of central Poland is perhaps epitomized by the remarkable excavations of an Iron Age fortified settlement at Biskupin near Bydgoszcz. Built upon a low-lying peninsula extending into a 100 hectare lake this timber-built settlement, dating from 550 BC, has been extraordinarily well preserved as a consequence of raised lake levels swamping the wooden foundations. 35,000 stakes of oak and pine formed a palisade around the camp, which covered an area of about 2 hectares and within which were rows of wooden buildings, over 100 in all. The population was largely agricultural, growing wheat, barley, millet, beans, lentils and flax, and this arable emphasis, coupled with the timber necessary to build such a construction, must have involved extensive deforestation of the surrounding region. Which brings one back to the question of whether such forest clearance could have affected the hydrological regime in such a way as to lead to raised lake levels and the ultimate swamping of the settlement which finally led to its abandonment. Since this particular period in prehistory is generally believed to have been a time of increasing precipitation and lowered temperatures in northern Europe, this may have to remain just another palaeohydrological conundrum.

#### A particularly anomalous Seyfert galaxy

from J.H. Krolik

SEYFERT GALAXIES and their quasar cousins have provided much observational mash for the vats of theoretical speculation over the years since their discovery. A recent article by T. Heckman and B. Balick has thrown an especially juicy bucketful into this already potent brew. Ordinarily, what astronomers find extraordinary in these objects are the very large continuum luminosity (10<sup>43</sup>-10<sup>45</sup> erg s<sup>-1</sup> in Seyferts,  $10^{45}$  –  $10^{47}$  erg s<sup>-1</sup> in quasars) and the very strong, broad (103-104 km s<sup>-1</sup>) emission lines coming from an optically unresolved source believed to be no more than a few parsecs in size. In this new paper, attention is turned to extraordinary goings-on outside the nucleus of a Seyfert galaxy.

Heckman and Balick made vidicon pictures of the galaxy Markarian 335 with a series of interference filters covering bands centred on Ha and [O 111]λ5007, each 3,300 km s<sup>-1</sup> wide (FWHM), and extending in total over a range ±5,000 km s<sup>-1</sup> from line centre. Most of the line emission does indeed come from the galactic nucleus, but surprisingly, there is a significant flux in most of the observed wavelength range from regions clearly separate from the nucleus. Interpreting the emission as coming from a large photoionized nebula, the inferred mass of gas outside the nucleus is  $\sim 2 \times 10^8 \, n_{\rm c}^{-1} \, M_{\odot}$  and its kinetic energy  $\sim 2 \times 10^{58} n_e^{-1}$  erg, where  $n_e$  is its electron density in cm<sup>-3</sup>. Such a large mass of gas moving at such high speed has never been seen elsewhere.

The first question that comes to mind is the source of ionization to drive the Hα recombination radiation. Heckman and Balick check that it is plausible for the Seyfert nucleus to be supplying enough ionizing photons. Baldwin and colleagues2 previously showed that the nucleus of 3C 120 superionizes its H II regions. Here the Seyfert nucleus has a much more dramatic influence on its galactic environment.

The second question is the source of the gas. An obvious supposition, and one that Heckman and Balick consider, is that this gas is material that once radiated the nuclear broad emission lines but has now spread further out into the galaxy. Unfortunately, we have no clear way of telling whether the nuclear emission line clouds travel radially in, radially out, or go in any other direction. Some lines (for example, C (v) 1549) have profiles which are easy to measure, but are emitted isotropically, and so tell us nothing about cloud kinematics. On the other hand, those lines, such as La, which are emitted only from one face of a cloud<sup>3</sup> are often so distorted by blending or intervening absorption that their usefulness is destroyed. Therefore, the presence of this gas may be as good an indication that at least some Seyfert nuclei expel gas some of the time as asymmetry of nuclear emission line profiles.

Once the possibility of a nuclear origin for this gas is admitted, many other questions instantly arise. Why did the expulsion last only for 106 years (its kinematic age)? Seyfert galaxies are generally supposed to live at least 108 years. Why did it occur only in Markarian 335, a galaxy which doesn't appear remarkable in any other way (but one, which we discuss in the following paragraph). In their kiloparsecs-long passage out into the galaxy, why haven't the clouds been appreciably slowed by drag? Why is the shape of the nebula so strongly asymmetric?

The final, and perhaps most interesting, question stems from Heckman and Balick's measurement of the radial profile of the galaxy's continuum emission. They find that the surface brightness declines away from the centre in a way more characteristic of elliptical galaxies than spirals. If Markarian 335 is an elliptical galaxy, it would be the only such Seyfert galaxy known; all other Seyfert galaxies whose types have been determined are spirals. Ordinarily, when an elliptical galaxy has a line-emitting nucleus, it is also a bright radio source, which Markarian 335 is certainly not. On the other hand, Seyfert galaxies sometimes do evince small-scale radio emission near their cores4. VLA observations of this unusual Seyfert galaxy might be a particulary fruitful next set.

#### The 1980 geomagnetic reference field

from David R. Barraclough

GLOBAL descriptions of the geomagnetic field are useful for many scientific purposes as well as being important in navigation. Traditionally, the information has been displayed by means of charts showing isolines of the geomagnetic element in question. Whilst this is adequate and even desirable for many navigational purposes, it has disadvantages for scientific use. During the last quarter of a century mathematical models of the geomagnetic field have been produced in large numbers to meet the needs of scientists and modern World Magnetic Charts are themselves

produced using such models as the first stage in the compilation process.

In almost all cases, the modelling technique used is the expansion of the geomagnetic field in terms of spherical harmonics. In this method, pioneered by Gauss almost 150 years ago, the potential (V) from which the geomagnetic field is derivable is expressed (equation (1))as

$$V = \alpha \sum_{n=1}^{N} \frac{n}{(\alpha/r)^{n+1}} \sum_{m=0}^{n} (g_n^m \cos m\phi + h_n^m \sin m\phi) P_n^m(\theta)$$

Here,  $\alpha$  denotes the radius of a reference sphere, usually taken to be the mean radius

(6,371.2 km) of the Earth, r the geocentric radial distance,  $\theta$  the geocentric colatitude and  $\phi$  the longitude of the point at which the potential is to be found and  $P_n^m$  ( $\theta$ ) denotes the associated Legendre function of degree n and order m. For a complete description of the Earth's magnetic field the series in equation (1) should extend to  $m=n=\infty$ , but in practice the series is truncated at a maximum value (N) of m and n, usually in the range n to n the geomagnetic field and its components can then be derived by taking the gradient of n as given by equation (1). harmonic model of the geomagnetic field thus consists of the N(N+2) coefficients  $g_n^m$ ,  $h_n^m$   $(m=0, 1, 2, \ldots, n; n=1, 2, \ldots, N)$  in equation (1).

Because of the relatively low truncation levels used, such models represent the parts of the geomagnetic field with wavelengths upwards of several thousand kilometres, that is, that part of the field which originates, in the main, from sources in the Earth's fluid core. This so-called main field is important in ionospheric and magnetospheric studies, in cosmic-ray physics and in studies of magnetic anomalies caused by crustal rocks. Magnetic anomalies can give valuable information about mineral resources but it is necessary to remove from the observations a realistic regional field so that the shorter wavelength crustal structure can be revealed. In the past, such regional fields were usually derived in an ad hoc way for each individual area of interest and this gave rise to problems when anomaly maps of adjacent areas were combined.

As an aid to users, and in particular to those interested in the study of magnetic anomalies, the International Association of Geomagnetism and Aeronomy (IAGA) adopted, in 1968, an International Geomagnetic Reference Field (IGRF) describing the main geomagnetic field at 1965 by means of 80 spherical harmonic coefficients (N = 8). Since the field changes with time, an additional set of 80 coefficients describing the secular variation was also included to extend the period of usefulness of the model. By the early 1970s it was becoming obvious that inaccuracies in the secular variation coefficients were causing unacceptably large errors in field values computed for current epochs from the model and the IGRF was revised by IAGA in 1975. This revision was limited to the provision of a revised set of 80 secular variation coefficients to be used for deriving field values for dates after 1975, the original and revised versions of the IGRF being continuous at 1975. With the passage of time this revised model has itself become inaccurate and a second revision of the IGRF was made at the IAGA Assembly held in Edinburgh last August.

The new version of the IGRF consists of five component models: four models of the main geomagnetic field for 1965, 1970, 1975 and 1980 and a model of the secular variation valid for the interval 1980 to 1985. The four main-field models each consist of 120 coefficients (N=10) whilst the secular variation model has, as before, 80 coefficients. The values of the coefficients are given in the Table. The constituent models have been derived by taking weighted means of three sets of candidate models, one each from the Institute of Geological Sciences in the UK, NASA (Goddard Space Flight Center) in the USA and the United States Geological Survey. The main-field models for 1965.

1970 and 1975 are designated Definitive International Geomagnetic Reference Fields (DGRF 1965, DGRF 1970 and DGRF 1975, respectively) since further revision is not envisaged. Linear interpolation between neighbouring models is to be used for dates that lie between the epochs of the models. The main-field model for 1980 and the secular variation model for 1980-85, which together constitute IGRF 1980, will be revised at a later date, probably about 1985. For dates between 1975 and 1980 a Provisional International Geomagnetic Reference Field (PGRF 1975) is defined by linear interpolation between DGRF 1975 and the main-field coefficients of IGRF 1980. For the interval 1980 to 1985, the main-field and secular variation coefficients of IGRF 1980 are to be used, according to the expression

C(t) = C(1980) + C(t-1980) where t denotes the date, C a main-field coefficient and C the corresponding secular variation coefficient. All coefficients are given in the Schmidt quasinormalized form and refer to a sphere of radius 6,371.2 km. For conversion from

geodetic to geocentric coordinates the use of the International Ellipsoid is recommended. This ellipsoid has an equatorial radius of 6378.160 km and a flattening factor of 1/298.25.

Computer programs for synthesizing field values and coefficients of the IGRF in computer-readable form are available from the following data centres: World Digital Data Centre Cl, Geomagnetism Unit, Institute of Geological Sciences, Murchison House, West Mains Road, Edinburgh EH9 2LA, UK; World Data Center A, National Oceanic and Atmospheric Administration, EDIS/NGSDC (D62), 325 Broadway, Boulder, CO 80303, USA; World Data Center A for Rockets and Satellites, Code 501, NASA/Goddard Space Flight Center, Greenbelt, MD 20771, USA.

The evaluation of the candidate models and the specification of the revised IGRF were the responsibility of Working Group I-1 (Chairman, N.W. Peddie) of IAGA.

David R. Barraclough is Co-chairman of the IAGA Working Group I-1 at the Geomagnetism Unit of the Institute of Geological Sciences, Edinburgh.

# Meteoritics — more facts, more complexity

from R. Hutchison and C.T. Pillinger

A recent meeting of the Meteoritical Society\* opened with a commemorative address for Harold Clayton Urey who died earlier this year, delivered by one of his former students, G.J. Wasserburg. The same speaker also gave the last lecture which looked into the future. His message, think isotopes and study only precisely characterized samples instead of random and heterogeneous bulk specimens, would undoubtedly have been approved of by his mentor. Meteorites are complicated objects (they seem to get more complicated all the time) recording chemical and physical processes which occurred before, during and after formation of the Solar System. They will only be divested of their information by much detailed research.

Between Wasserburg's opening and closing remarks, another former Urey student, Sam Epstein, reviewed data obtained by himself and F. Robert at Caltech concerning the deuterium/hydrogen ratios and other stable isotope compositions of the carbonaceous polymers of C1 and C2 chondrites which revealed that some fractions had several times more deuterium than terrestrial samples. This is an astounding result when compared to the parts per thousand

R. Hutchison and C.T. Pillinger are in the Department of Earth Sciences, University of Cambridge. deuterium/hydrogen variations occurring on Earth.

Not to be outdone, N.J. McNaughton et al. (University of Cambridge) reported that for almost all the water extracted from bulk LL3 ordinary chondrites Bishunpur and Semarkona, the deuterium content was at least as high as that from the carbonaceous meteorites. Starting with samples like these, Urey might have made his Nobel Prize-winning discovery of deuterium a little earlier. The consensus of opinion was that deuterium enrichments are the result of ion-molecule reactions occurring in dark interstellar clouds and that a component from this source has survived within the Solar System as a heterogeneity in primitive meteorites.

Clearly, the deuterium story needs some of that painstaking effort demanded by Wasserburg. An example worth emulating is that of Ne-E, the almost pure <sup>22</sup>Ne, thought to be the daughter of short-lived <sup>22</sup>Na, which was first discovered in 1969. Thanks to the efforts of the Eberhardt group at Berne, who performed X-ray powder diffraction studies and semi-quantitative analysis during scanning electron microscopy, another of the host phases of Ne-E seems now to have been identified as a hydroxy or fluorapatite.

\*The 44th meeting of the Meteoritical Society was held at Berne, Switzerland, August 17–22, 1981.

Thus the parent <sup>22</sup>Na presumably was located in spinel, in a carbonaceous substance<sup>2</sup> and in apatite — the reasons for these diverse associations are not yet forthcoming.

Whilst the existence of a material which predates the Solar System is appearing more and more likely from Ne-E studies, the possibility that the Allende meteorite contains inclusions with ages up to 5,200 Myr — half a billion years older than the Solar System — appears to be receding. Employing the simple but elegant method of measuring the gas after irradiation, in a sealed ampoule, J.C. Huneke and I.M. Villa (Caltech) succeeded in showing that exceptionally high losses of <sup>39</sup>Ar (up to 65 per cent) can occur from fine grained Allende inclusions, probably by diffusion after recoil out of the fine grains into the grain boundary voids. E. Jessberger (Max-Planck-Institut für Kemphysik, Heidelberg), speaking on behalf of the group which reported the 'aged' Allende inclusions3, stated that appropriate repeat measurements would be performed with the added precaution of shielding from thermal neutrons in case these have some detrimental effect.

Changing views on the origin of Ca-Al rich inclusions in Allende and other carbonaceous chondrites were made clear by the reception given to G. Kurat's invited lecture. Eight or ten years ago, an origin by condensation was almost totally accepted for high temperature inclusions. Kurat (University of Vienna) was one of the few dissenters. Now, origins as melts, condensates and residues from evaporation are all considered, depending on the relevant chemical and textural characteristics of each.

There was much debate on the validity and refinement of estimates of cooling rates of meteorites based on different techniques4. Such information may be useful in determining minimum sizes for the parent planets of meteorites. K.H. Esbensen and V.F. Buchwald (Technical University of Denmark) showed that a 20 ton iron of the Cape York shower had formed by fractional crystallization from an Fe-Ni-S-P liquid down to about 700°C. Moreover, some of the products had not been significantly altered by solid state diffusion during subsequent cooling. Considerable chemical variation among the Cape York shower was described (D.J. Malvin and colleagues, UCLA), arguing against formation by simple fractional crystallization whilst part of the small planetary core thought to have been parental to all irons of group IIIAB.

R. Hutchison et al. (British Museum) defended their hypothesis<sup>5</sup> of hot accretion and rapid cooling for the formation of H-group chondrites, one aspect of which was questioned by J. Willis and J.I. Goldstein<sup>6</sup> (Lehigh University). A discrepancy between the metallographic cooling-rate (0.5°C Myr-1) and the Pufission cooling rate (> 3.8°C Myr<sup>-1</sup>) of the Marjalahti pallasite was announced by P. Pellas and colleagues (Museum d'Histoire Naturelle, Paris). If the latter is confirmed it would remove the inconsistency of the planetary core (IIIAB irons) seeming to have cooled faster than the core/mantle interface (main group pallasites) which is its outer boundary.

The importance of recent Antarctic meteorite finds provided a recurrent theme of the meeting. Collections of samples from areas of blue ice on the Antarctic continent by US and Japanese expeditions seemed to be offering meteoriticists guaranteed employment for some time to come. As detailed studies have got under way, however, it transpires, not unexpectedly, that many samples are paired and are thus representative of meteorites which fragmented7. Both S.G. McKinley (Albuquerque) and M. Honda (Tokyo) provided invaluable pairing information which should save colleagues unnecessary duplication.

The recovery and mechanisms of concentration of Antarctic meteorites were discussed by L. Schultz et al. (Mainz) and J. Annexstad (Johnson Space Center, Houston). One factor is wind, which can blow masses of up to 20 g across bare ice, to be concentrated at the snow covered margin. Earlier hopes of obtaining a supply unweathered meteorites from Antarctica have been dashed over the past few years. An example was presented of a small, dark stone sitting in a pool of water. although the air temperature was -20°C! However, as long as samples are unweathered, even though they may have spent a lengthy period on the ice cap before recovery, they may be considered as uncontaminated in terms of trace elements, like museum specimens observed to fall and immediately collected and carefully preserved (M.E. Lipshutz, Purdue).

Another facet of the paper by Honda was that the terrestrial ages of Yamato meteorites range from  $10^4$  to  $7 \times 10^5$  years, the mean life of an Antarctic meteorite probably being about  $2 \times 10^5$  years. Our sample of ancient meteorites from Antarctica is essentially the same as that from the rest of the world.

Several rare or unique meteorites have been recovered. H.Y. McSween and A.M. Reid (University of Cape Town) described the first observation in a meteorite of a contact between two primary, igneous lithologies, which probably formed in a single magma chamber. From the other side of Antarctica came a 189 g meteorite intermediate in composition between diogenites and eucrites (H. Takeda and H. Mori, Tokyo). Finally McKinley and colleagues (University of New Mexico) described a 'unique' unequilibrated, L3, chondrite from Allan Hills. The stone is unusual in that it contains both magnetitegraphite and silicates in the matrix, and so is intermediate between 'normal' unequilibrated ordinary chondrites and a recently discovered graphite-magnetite rich variety8.

#### 99 years ago

The Japan Gazette of August 21 contains a long and curious description of a bear festival among the Ainos. The writer, Dr. B. Scheube, is, we believe, the only European who has ever been actually present at this ceremony, the descriptions of it given by Miss Bird and other writers being derived from hearsay. The festival is now rarely held, and there is small reason to regret this, as it has degenerated to a brutal orgy. It commences with drink, every change in ceremony begins and concludes with drink, until finally every one in the village is intoxicated, while their hands, faces, and clothes are smeared with the gore of the sacrifice. Dr. Scheube says: "I had much difficulty in keeping off the drunken crowd that wanted me to partake of the blood and liver (the latter is eaten raw); and I can say that though hardened in these things by the practice of my profession, the sight of these drunken people with their bodies smeared over with blood filled me with a loathing that made me feel glad that the day and the feast were

coming to an end together". Dances, many of them of an obscene nature, also form part of

Mr. Stanley has published separately a full report of the address he recently gave in Paris. From this we glean one interesting item of exploration. After he had launched his steamer on the upper waters of the Congo, above the cataracts, he proceeded up the river and entered the Kwango, the great southern tributary. One hundred miles from its mouth he came to where two large streams united to form the main river; a greyish-white stream from south by east, the other, of an inky colour, from east by south. Ascending the latter, much less rapid than the former, Mr. Stanley came, after steaming another 120 miles, to a large lake, into which the river widened. On circumnavigating it, he found it about seventy miles in length, and with a breadth varying from six to thirty-eight miles. The natives he found very wild, and naturally astonished at the puffing monster. A splendid country the shore seemed to be impenetrable - lofty forests, alternating with undulating grass lands. Mr. Stanley was altogether three years away from Vivi, and doubtless he has collected much information in the country around the Congo.

#### Monoclonal Antibodies in Endocrine Research

Editors: R. Fellows and G. Eisenbarth

This highly informative volume focuses on the growing importance of monoclonal antibodies in endocrine research and on the recent rapid expansion in the use of hybridoma technology to produce specific antibodies in quantity. Several significant advances in monoclonal antibody technology are discussed, including the development of a human myeloma cell line which can be fused with circulating human lymphocytes to produce monoclonal antibodies of defined specificity. The uses of monoclonal antibodies for immunoassay, radioimmunoassay, immunocytochemistry, immunoaffinity purification, and as probes of hormone and receptor structure and function are explored.

208 pages, \$23.00 (1981) ISBN 0-89004-687-5 (Order Code 1067)

#### Ion Transport by Epithelia

(Society of General Physiologists Series, Volume 36)

Editor: S. G. Schultz

Until recently, the study of ion transport by epithelial tissue was dominated by efforts to characterize the overall transport properties of epithelial tissues, primarily through the use of the "black box" techniques and theory. It has recently become apparent, however, that "black box" approaches provide little information on the detailed mechanisms underlying ion transport. To fully understand these mechanisms, attention must be directed toward defining the properties of the individual membranes or barriers that make up epithelial tissues and the properties of the intracellular compartment(s).

This volume focuses on recent approaches to defining the mechanisms underlying ion transport. Emphasis is placed on insights into the properties of the transporting cell derived using conventional microelectrophysiologic techniques and ion-selective microelectrodes.

287 pages, \$32.00 (1981) ISBN 0-89004-610-7 (Order Code 615)

#### Organelle Heredity N. W. Gillham

"The book is the most thorough treatment yet of mitochondrial and plastid genetics, and deserves to be read widely by geneticists, biochemists, cell biologists, and advanced students.... This well produced book, with its ample references, is a milestone in the history of genetics." — Nature

618 pages, \$53.50 (1978) ISBN 0-89004-102-4 (Order Code 196)

#### Pathophysiology of the Reticuloendothelial System

Editors: B. M. Altura and T. M. Saba

Reviewed in this text are the fundamentals of the biology of the reticuloendothelial system. It presents the results of *in vivo* and *in vitro* observations ranging from molecular to clinical, to illuminate the various metabolic, physiologic, immunologic, and pathologic roles of this complex collection of phagocytic cells.

241 pages, \$24.00 (1981) ISBN 0-89004-441-4 (Order Code 502)

#### Pathobiology Annual, 1981 Editor: H. L. loachim

Continuing in the tradition of the **Pathobiology Annual** series, this volume assembles critical reviews in a broad spectrum of biomedical subjects. Topics include the regulation of gene expression in normal and neoplastic cells; the pathogenesis of gestational trophoblastic neoplasms; the pathogenesis of sickle cell disease; the biology of endorphins and opiate receptors; complement-mediated inflammatory reactions; and the structure, biosynthesis, and pathogenic implications of Tamm-Horsfall uromucoprotein, which has been implicated in a variety of urinary tract diseases.

Approximately 425 pages, tentatively \$42.50 (December 1981) ISBN 0-89004-571-2 (Order Code 669)

#### **Membrane-Membrane Interactions**

(Society of General Physiologists Series, Vol. 34)

Editor: N. B. Gilula

This volume examines the molecular mechanisms involved in generating and maintaining interactions between membranes in various biological systems. The first section, on membranes and model systems, deals with contemporary studies of membrane structure and biosynthesis, including studies on cell fusion with an experimental model system. This is followed by a discussion of biological systems in which membrane-membrane interactions are transient, e.g., secretion, the acrosomal reaction, cell fusion, virus-membrane fusion, mating, and fertilization. The final section reviews three biological areas in which membrane interactions are static over a prolonged period of time: intercellular junctions, chloroplast membrane interactions, and myelin.

#### The Molecular Basis of Antibiotic Action, 2nd Ed.

by E.F. Gale, Department of Biochemistry, University of Cambridge; E. Cundliffe, Department of Biochemistry, University of Leicester; P.E. Reynolds, Department of Biochemistry, University of Cambridge; M.H. Richmond, Department of Bacteriology, University of Bristol, and M.J. Waring, Department of Pharmacology, University of Cambridge

Summarizes our present understanding of the mechanisms by which antibiotics work. It stresses those interactions which enable antibiotics to act selectively, first describing various biochemical targets for drug action, then, covering in detail, agents which act against cell walls, cytoplasmic membranes, nucleic acids and ribosomes. The reader is also given a framework for understanding the molecular basis of bacterial resistance to drugs, and an assessment of the prospects towards a rational approach to chemotherapy.

## Some Perspectives of the Major Biogeochemical Cycles,

edited by **G.E. Likens, S**ection of Ecology and Systematics, Division of Biological Sciences, Cornell University

The increasing alteration of global cycles by human activities has now reached a critical stage where the distortion may in fact equal or exceed present-day natural fluxes for certain elements (eg. sulphur and carbon) or processes (eg. erosion). This book is a first attempt at a holistic consideration of global cycles. It points to some of the interactions between cycles, raises many of the questions and problems of empirical measurement and socio-economic impact, provides some future directions for research and monitoring, and lists some important goals.

The papers contained in this volume were originally presented at a Symposium held in Stockholm in June 1979 initiated by the Scientific Committee on Problems of the Environment (SCOPE), with the intention of synthesizing many of the themes covered in the numerous previous workshops and symposia sponsored by SCOPE on global cycles.

#### **Ocean Wave Energy Conversion**

by M.E. McCormick, U.S. Naval Academy

Provides a review of ocean wave mechanics and an introduction to wave energy conversion. It includes physical and mathematical descriptions of the nine generic wave energy conversion techniques, as well as several electro-mechanical energy conversion techniques and possible environmental effects associated with wave energy conversion. It also includes worked examples, and contains selected patents, terminology and an extensive bibliography.

Alternate Energy Series

#### **Recent Advances in Prenatal Diagnosis**

edited by **C. Orlandi,** University of Bologna, Italy; **P.E. Polani,** Paediatric Research Unit, Guy's Hospital, UK, and **L. Bovicelli,** University of Bologna, Italy

The book's aim was to present, by means of international cooperation and exchange of information, an account of the most recent developments in the field of prenatal diagnosis. Particular emphasis was given to diagnostic aspects, such as ultrasonic and obstetric techniques, and to genetic aspects such as chromosome errors, inborn errors of metabolism and neural tube defects. The recent application of prenatal diagnostic techniques to musculo-skeletal diseases was also considered as were the conditions requiring direct investigation of the fetus and fetal blood.

As an aid to disease detection, prenatal diagnosis is a significant development in the advancement of our understanding of disease mechanisms. There is strong evidence to suggest that the group of techniques currently employed will therefore be relevant to the diagnosis of an increasing number of diseases. Proceedings of the First International Symposium on Recent Advances in Prenatal Diagnosis, Bologna, September 1980. September 1981

September 1981 34450/£19.75 \$44.50/£19.75

#### **Aquatic Chemistry:**

An Introduction Emphasizing Chemical Equilibria in Natural Waters, 2nd Ed.

by W. Stumm, Swiss Federal Institute of Technology, and J.J. Morgan, California Institute of Technology

Examines a theoretical basis for the chemical behaviour of ocean waters, estuaries, rivers, lakes, groundwaters, and soil water systems. This book covers the processes involved in water treatment, comparing real systems with idealized counterparts or models. It discusses chemical processes affecting the distribution and circulation of chemical substances with an ecological perspective on pollution and its control. It also shows the application of elementary principles of physical chemistry, the interplay of chemical equilibria and kinetic considerations, in isolating and identifying some of the variables which affect the composition of the water. Numerous graphs and illustrations are included.

July 1981 0471 04831 3 0471 09173 1 796pp (cloth) \$59.85/£33.25 (paper) \$31.60/£17.60

#### **Introduction to Alkaloids:**

A Biogenetic Approach

by G.A. Cordell, University of Illinois, Chicago

Summarizes the occurrence, synthesis, biosynthesis, spectroscopic properties, chemistry and pharmacology of all the alkaloid groups. The introductory chapters treat the history, detection and isolation techniques, and the formation of alkaloid precursors; subsequent chapters are organized according to the biosynthetic precursor of each alkaloid group. It presents all major synthetic pathways and contains extensive tables of spectroscopic data.

#### AUTUMN BOOKS SUPPLEMENT

## Who will write more books?

BOOKS have an odd place in the scientific literature. The institution of the book, especially when bound in hard covers, still commands general respect. Most books, after all, are the products of hard work and devotion by one or a few people. And not merely authors but attempted authors know how lonely their work is, and how it may give hostages to fortune. Yet some books have a lasting influence. Newton's *Principia* and Darwin's *Origin of Species* are but the most conspicuous if almost hackneyed examples.

Books are also, however, widely suspected. And with some reason. Although few books are now published entirely without the benefit of external criticism, peer review does not apply as formally as to articles published in the journals. Often, indeed, the authors of books appear to shoulder responsibility for external review themselves, thanking a small group of friends for help and advice immediately before the ritual disclaimer in most prefaces that only the author should be blamed for the errors that survive. And while some publishers may take great pains to ensure that manuscripts are read with care, and revised if necessary, the procedures of formal review are not uniform either between publishers or books, and are rarely in any case explicit. This is the sense in which books are often regarded as peripheral to the scientific literature proper.

Accordingly there is a temptation among professional people to suppose that books are somehow half-way between Apocrypha and light entertainment, in contrast to the measure of respect accorded to at least some journals. Books, then, are at a disadvantage in professional esteem compared with articles in the journals — a sad reversal of the traditional opinion that printed books are in some permanent way the embodiment of scholarship. So journals now command the attention of authors, who are reluctant to put more than a few thousand words on paper. Moreover, the scorn of books as vehicles of scholarship is probably greater among scientists than among other professional scholars.

It is high time that this balance was redressed. The importance of the journals in the scientific literature will not easily be undermined, and there is no reason why it should be, whatever the prospects ahead for electronic publishing and the like: but the value of printed books, especially those by a single author or by a few close collaborators is now too little appreciated. The result is that people's natural disinclination to suffer the pains of authorship for no immediate recognition is strengthened. The symposium of reviews of books that appears on the following pages may persuade some whose disenchantment is not permanently rooted that these neglected scholarly forms do indeed require more careful nourishment.

The most important need is that the contribution of books not merely to the education of students but of contemporaries should be more widely appreciated. Although most professional people are aware in their own education of the influence of particular books which seemed at first to be a means of coming to grips with some body of knowledge, and which later turned out to be a lasting challenge, it is now all too common that students, even undergraduates, are provided not with a book but with a list of references to articles in the journals (or even, illegally, with copies of them) and invited to make up their own books in their heads. By way of justification, it is often argued that this practice not merely teaches students about their subjects but that it also enables them to understand what research is like. This, however, is a thin excuse for many teachers' laziness.

A good textbook differs from the most carefully chosen set of

references in several obvious but nevertheless crucial ways. First, it will have a sense of history that cannot be conveyed by a list of dates. Second, it will judiciously assess the importance of contributions to some field of study. But it will also be challenging, stimulating and — ideally — original. Even in the most rapidly changing fields, good books for students have an element of reflectiveness of necessity absent from articles in journals. The appearance of Feynman's Lectures in Physics in the 1950s was a good illustration of how the very best textbooks become required reading for fellow-teachers as well as students. But, teachers will complain, good up-to-date textbooks simply do not exist in quickly moving fields. The remedy, they must know, is in their own hands, or pens.

Another common complaint is that there are too few scholarly reviews in the scientific literature. Over the years, especially in the United States, a succession of committees has considered how to encourage working scientists to withdraw for a time from the bench or the competition for space in the ordinary journals to distil their knowledge of a field or topic into a reflective review. Several remedies have been suggested. Review journals might help. So might fees for authors. In some fields these policies have worked well, sometimes commercially - without the need of subsidy. The results are widely appreciated, not only by people reading their way into a subject but by the scientific community as a whole. Yet the argument that there should be more reviews, and that scientists should be more willing to produce them, is only a part of the much stronger argument that there is an urgent need of more books, and that they too are a charge on people's professional responsibility. For books have the advantage over journals that they are — at least soon after publication — more accessible, more portable and more memorable. But who except professional scientists can meet the need to which they so often draw attention?

These didactic goals are the bread and butter of scholarship. But are the monumental books differently conceived? Not necessarily. Newton's *Principia*, indeed, reads as if it were a textbook, with its lemmas, theorems and the like; it was, after all, intended to instruct. And it is easy to see how the *Origin of Species* might have begun as a scholarly review of what was known, in the mid-nineteenth century, of the relationships between species. But in the end the result was a thesis. The moral is that even quite pedantic exercises in authorship may turn out to help to change the world. That is part of the fun, now apparently much neglected.

For many people, however, the potential excitement of authorship is outweighed by what are often considered to be the dangers inseparable from books. For books lend themselves to reflectiveness and also, unfortunately, to discursiveness. Thus they tempt authors into subjective judgements of other people's work, even to speculation. Is that not a temptation to resist, potential authors ask themselves? And is it not in any case dangerous to be published in a format which, it is well-known, includes much unfounded speculation hung loosely on a mass of unrefereed data, unestablished assumption and tendentious argument? The implied criticisms are unfortunately occasionally applicable. The conclusion is not, however, that all books are bad but merely that some are bad. Others, everybody knows, are at the other end of the spectrum. And their absence would impoverish the scientific literature as a whole. Is it not therefore time that the scientific community stopped complaining about the scientific literature and instead set about adding to the quality of that part of it which has been most neglected in the past few decades?

## The making of a modern museum

#### William Coleman

THE British Museum was largely the product of a single dazzling collection and the intention of an indefatigable collector, Sir Hans Sloane. Soon, however, that collection and the Will that transferred it to the British nation faced unexpected and, hindsight makes clear, increasingly unwelcome competition. Sloane had primarily collected natural objects plants, animals and minerals - and an associated library. Late in life he proposed that these materials, suitably housed and cared for, should form a repository in which his fellow countrymen could, as Robert Hooke had earlier declared of the Royal Society's museum, "read the book of nature" itself. But conflict was inherent in the very act of creation of the British Museum (1753). Sloane's treasures were confounded with two additional and equally remarkable collections: The Cottonian library and the Harleian MSS. Here were books and documents, important artefacts of human culture, that became and remained formidable rivals of the artefacts of nature.

Until 1880 these varied materials and numerous others, particularly archaeological objects and monuments of early European civilization, slept together in crowded confines in Bloomsbury. Their coexistence pleased few. Antonio Pazzini, Principal Librarian (that is, senior executive officer), was an imperious administrator and the impassioned developer of the Museum's printed materials and manuscripts, the heart of today's British Library. Until 1856 the scientific collections possessed no comparable advocate. From that date, Richard Owen, anatomist, zoologist and skilful political manipulator, directed a course that led to the opening, on 18 April 1881, of Alfred Waterhouse's visually superb new home for the scientific collections. The move to South Kensington in 1880-1883 thus provided physical autonomy for the natural history collections; complete independence (except for its cumbersome name) came only in 1963 when Sloane's original foundation was divided and the British Museum (Natural History) acquired its own board of trustees, including a majority of scientists.

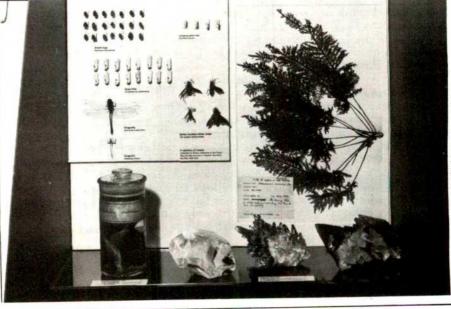

W.T. Stearn and A.E. Gunther, in dissimilar but complementary books, record in abundant detail the many and often complex developments and conflicts that produced today's British Museum (Natural History). Stearn's is a truly comprehensive

The Natural History Museum at South Kensington: A History of the British Museum (Natural History) 1753–1980. By William T. Stearn. Pp.496. ISBN 0-434-73600-7. (Heinemann: 1981.) £15. The Founders of Science at the British Museum, 1753–1900. By A.E. Gunther. Pp.219. ISBN 0-950-72760-1. (Halesworth, Suffolk, UK: 1980.) £9.90, \$20.

account, dealing with all aspects of the institution: Gunther explores, largely biographically, selected scientific work carried out by the staff at the Museum during its early years. Printed materials, official and unofficial reports and memoranda, correspondence and scientific publications provide the basis for these volumes. Gunther refers briefly and adequately to his sources but Stearn, alas, one of the foremost students of the bibliography of natural history, provides no overall guide to the marvellously diverse materials that he has consulted; his references lie scattered throughout the text and will need to be extracted by each reader as occasion dictates. Both volumes are well illustrated, the authors' selection of pictures affording a view of most features of the Museum's activities, including curation, exhibition and administration. Also valuable are the several appendices offered by each author, listing chronologically persons and major events associated with the Museum.

A museum, particularly a museum as important and well frequented (two to three million visitors per annum) as is the British Museum (Natural History), constitutes a diverse and expensive institution that inevitably must try to serve many masters. Its public face may appear orderly and calm but its private life is one of sharply differing opinions and compromise, the latter often offering satisfaction to few or none. Gunther and especially Stearn provide a record of the struggles, some personal and others substantive, that have constantly beset the Museum but neither author provides a sustained general consideration of the one issue that remains in question in all seasons, namely, what are and should be the principal functions of a (natural history) museum and how are these goals best to be realized.

Preservation and exhibition of specimens were intrinsic to Sloane's conception of a national museum; the further purpose of increasing the collections in size, and ultimately in systematic diversity, was added in later years. Only slowly did the British Museum (Natural History) come to view scientific research and technical advising as part of its concern. The example and the constant urging of John Edward Gray (1800-1875) encouraged this trend, one that required appointment of a competent scientific staff. But this was a matter for long years of no particular interest on the part of the Trustees. Such concerns continue, of course, and the demands that they pose are only heightened when limitations on staff,

urtesy of the Trustees of the British Museum (Natural History)

The public's view of the Natural History Museum in the 1980s. Opposite — part of the "Nature Stored: Nature Studied" exhibition, a display in a more traditional mould. Above left — the artefacts of nature remain, but push-button displays obtrude in the "Man's Place in Evolution" exhibition. What would Richard Owen (right) have made of it all?

funds and space become severe. The latter is a chronic museum problem and one often felt by the British Museum (Natural History). Confusion of function has been further compounded by the perceived tastes of the television generation: museum exhibitions and popular publications admittedly seek the lower end of a vague average intellect. They seek their market, attendance having become a crucial statistic with which to defend old support and to solicit new funds, by offering gentle instruction and mounting increasingly brilliant displays. Old values have in the process been transformed and the new product - the word fits well - is perplexing.

In this world agog with educational technology and associated display techniques, one must ask a foolishly obvious question - what use the artefact itself? It was the very object whose protection was the minimal original objective of any serious natural history collection, yet many modern displays, including the "spectaculars", offer more aluminium and plastic than rock, cellulose or flesh, however dry. Study collections, the hard core of a museum in confident times past and today, as extinctions proceed apace, one of our few hopes for further increasing our understanding of the career of life on this globe - occupy the back room; the public is given a glance at most. The moral is obvious: as display divorces itself from artefact, so might this circus in miniature easily and effectively separate itself from a central museum. Modern displays are instructive and entertaining but they are also reproducible; they can play in Palermo or Peoria as well as in London or New York. So perhaps they should, while the central museums redirect their limited resources to the care, study and display of the genuine objects of natural history.

William Coleman is Professor of History of Science and History of Medicine at the University of Wisconsin, Madison.

## The grand Vernonian omnibus

Robert Fox

Gentlemen of Science: Early Years of the British Association for the Advancement of Science. By Jack Morrell and Arnold Thackray. Pp. 592. ISBN 0-19-858163-7. (Oxford University Press: 1981.) £30, \$59.

THIS summer, in York, the British Association for the Advancement of Science celebrated its 150th anniversary. There could have been no more appropriate location. For it was in York, in 1831, that some 350 "friends of science" set in motion what a friendly contemporary called "the grand Vernonian omnibus". (The reference was to the Revd William Vernon Harcourt, the son of the Archbishop of York and the central figure in the task of foundation.) By 1844, when the fourteenth of its peripatetic annual meetings took place, once again in York, the BAAS had completed a circuit of the main traditional centres of British cultural life - Oxford, Cambridge, Edinburgh and Dublin (London, then as now, being excluded as a possible venue) - and of some of the bigger industrial cities. On the way it had given unprecedented visibility to the scientific enterprise and signally advanced the incipient sense of community among Britain's men of science. Oxonians and Cantabs, manufacturers and clergy, military men and doctors, peers and politicians, even some women, had become united in an organization whose seemingly easy commitment to the value-free universalism of science in reality carried a carefully constructed ideology.

Gentlemen of Science is a meticulous study of the first 13 years of the BAAS, in

which these successes were achieved. They were decisive years for science in Britain: the neologism "scientist" won acceptance, and more importantly, as Morrell and Thackray argue, the very idea of science as a distinct form of knowledge, at once benign, powerful and progressive, was articulated. In the process, Harcourt's Baconian conception of the Association as a vehicle for the predominantly empirical work of his fellow provincials gave way to a rival conception, emanating from London and Cambridge, which stressed the primacy of theory and mathematics. Inexorably, it seems, the intellectual weight of the Association drifted towards Section A (mathematical and physical science), and it was in mathematical physics that the early BAAS established its most distinctive and coherent tradition of research. Moreover, as mathematical physics rose in the BAAS hierarchy of the sciences, the biological and social sciences - agriculture, ethnology and geography, for example fell, while phrenology and education were among the would-be sciences that were edged out altogether. Even medicine succumbed as the Association's leaders took upon themselves the task of defining "science": it was no coincidence that the medical section disappeared in 1848.

The waters which the BAAS chose to sail were often choppy. Tractarians and fundamentalists joined the most conservative elements in political life in seeing the organization as a rival claimant to the various areas of authority which they regarded as their preserve. Then there was always the problem of competing interests within its

ranks. How, in particular, did it find room for two such abrasive and mutually hostile personalities as Sir David Brewster and William Whewell, the former virtually unemployed and obsessed with the inadequacy of scientific patronage, the latter basking in the ample luxury of Trinity College, Cambridge? One answer seems to lie in the prosopography of the twenty Gentlemen of Science whom Morrell and Thackray identify as the ruling coterie of the BAAS (and who give the book its title). All but two of the twenty were Anglicans of a liberal or latitudinarian persuasion, and most of them were also Whigs or Peelite Tories with an interest in moderate reform. They were, in short, predominantly men of the centre, wedded to an ideal of conciliation and social harmony.

It is one of the most impressive achievements of this impressive book to relate the spirit of accommodation which pervaded the higher reaches of the BAAS to the political and social conditions of the troubled decades that separated the massacre of Peterloo (1819) from the Chartist National Assembly of 1848. With mob violence a real or potential threat, and with established institutions being questioned as never before, there was every

reason for the gentry and aristocracy to feel beleaguered. They needed allies, and so reached down the social scale to make common cause with an increasingly powerful educated middle class which shared the aristocracy's horror of wholesale revolution. In this quest for social integration, science was quickly recognized as a natural field for shared endeavour, if only because it was deemed to be of such varied utility, whether as uncontroversial rational amusement, as the foundation of Britain's industrial prowess (a particularly dubious claim at the time) or as the source of at least a limited understanding of God. After two or three decades in which, for all these reasons, the vogue for science had gripped polite society, in metropolis and provinces alike, the conditions for the success of the BAAS could hardly have been more auspicious.

Gentlemen of Science is the fruit of more than ten years of painstaking research, in the course of which thousands of previously unknown letters (300 of them soon to be published in the Royal Historical Society's Camden series) have been culled to exciting effect. The authors bear their immense erudition gracefully, ingeniously mingling detailed narrative with passages

of analysis, and succeeding brilliantly (where so many others have failed) in elucidating the constant interplay between the content of scientific knowledge and the context of its production. The book bristles with challenging interpretations. If only by implication, it tilts effectively at the canard, launched by contemporary Jeremiahs like Charles Babbage and still alive to this day, according to which British science about 1830 was in decline. Babbage was, of course, correct in stating that science in Britain did not have the level of state patronage that it enjoyed in France. But what he did not say was that many French savants were in turn envious of Britain's tradition of self-help. That the French were justified in their envy is made abundantly clear by Morrell and Thackray's account of the BAAS's achievements, whether as a forum for the discussion and dissemination of ideas or as a lobby in what was at the time the new game of hunting research grants.

At last the early history of the BAAS seems to make sense. Above all, it is to be hoped that historians will never again try to squeeze the devotees of British science in the 1830s and 1840s into the uncomfortable strait-jacket of conventional models of professionalization. The aim of the Gentlemen of Science was not the advancement of science as a means of livelihood; they regarded the study of nature as a vocation whose interests were more likely to be harmed than served by the fetters of full-time scientific employment. Hence there was nothing paradoxical about their enthusiasm for colourful public displays, ranging from the sparkling dinner which the Archbishop of York offered at his palace during the 1831 meeting, to the impromptu sermon which Adam Sedgwick delivered "to some 3000 or 4000 colliers and rabble" on the beach at Tynemouth (Newcastle upon Tyne meeting, 1838). There was nothing paradoxical either about the fact that independent men of science like the Marquis of Northampton and the retired stockbroker Francis Baily occupied as prominent a place in the BAAS leadership as university chairholders like Sedgwick, Whewell and Baden Powell. By their work for the BAAS, these men undoubtedly contributed to the establishment of science as a profession. But they did so unwittingly. Had they been at York this year, they would have marvelled at our modern paraphernalia of formal qualifications and rigid career-patterns. They might also have reflected that science is no longer quite the fun which this absorbing and entertaining book shows it was 150 years ago.

#### **LERRILE**

GIVEN BY THE

#### Magistrates & Town Council of Glasgow LIST OF TOASTS.

For the early members of the BA science was perhaps more funthan it is today, but must have had its tedious aspects. The illustration shows the list of toasts proposed at a dinner given for the Association by Glasgow Corporation in 1840.

Robert Fox is Reader in the History of Science at the University of Lancaster and President of the British Society for the History of Science. His most recent book, co-edited with George Weisz, is The Organization of Science and Technology in France, 1808-1914 (Cambridge University Press, 1980).

## In search of our place in the Universe

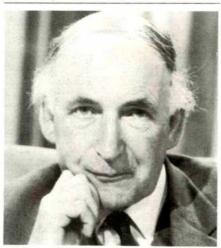

Joseph Silk

PHILOSOPHERS arise! Cosmology is beckoning. For mankind has found a niche in the Universe as it expands from an origin shrouded in mystery to an unknown future. Sir Bernard Lovell's new book tells the story of the development of human awareness of the Universe. Lovell leads us from the geocentric cosmology of the ancient world via the heliocentric cosmology of the Renaissance and the egocentric cosmology of the nineteenth century. His destination, of course, is the big bang theory of the expanding Universe, where fundamental issues still await resolution. Some of these issues differ little from the questions which faced the cosmologists of antiquity. Sir Bernard Lovell is an eminent radioastronomer who has no cosmological axe to grind, and it is especially refreshing to discover that his popular account of the evolution of cosmology manages to be both readable and enthralling.

We learn about the epicycles of Hipparchus and Ptolemy, and about how Thomas Aquinas incorporated Aristotle's crystal sphere cosmology into an apparently irrefutable argument for the existence of God. With Copernicus, the heliocentric hypothesis re-emerged and, against all odds, survived, while Tycho Brahe established the first accurate and systematic records of planetary data. Brahe punctured the immutable crystal spheres with his studies of comets and of the famous supernova of 1572. His assistant, Johannes Kepler, derived the laws of planetary motion after a painful decade of sifting endless mathematical permutations of the planetary data, and despite unflinching belief in the celestial harmony exhibited by the five regular solids. Next, Galileo's observations with a 4 cm aperture telescope caused an immense stir that led to an unavoidable conflict with the geocentric dogma upheld by theologians. Galileo saw sunspots, the moons of Jupiter and the phases of Venus, all of which established that the heliocentric system was a reality, and could no longer be thought of as a computationally convenient hypothesis. It remained for Isaac Newton to express the universal law of gravitation in a way that gave a theoretical understanding of Kepler's Laws.

The stage was set for modern astronomy. One of the great pioneers was William Herschel, who counted stars and mapped our Milky Way galaxy. Not, however, until the twentieth century was the Sun finally displaced from the centre of the Universe. Harlow Shapley resoundingly overthrew the egocentric view of the place of mankind in the Universe by using the newly calibrated period–luminosity relation for Cepheid variable stars to establish distances to remote globular star clusters. These were found to surround the

Emerging Cosmology. By Bernard Lovell. Pp.208. ISBN 0-231-05304-5. (Columbia University Press: 1981.) \$14.95, £10.80.

Sir Bernard Lovell, now tackling the history and philosophy of cosmology.

centre of our galaxy some 30,000 light years from the Sun. Much happened subsequently: the discoveries of the expansion of the Universe and of the cosmic microwave background radiation are two of the highlights that have now led cosmologists almost unanimously to adopt the big bang cosmological model.

All of this forms a backdrop to Lovell's theme, which is the evolution of cosmological thinking. Lovell's book forms part of a philosophical series entitled "Convergence" and founded, planned and edited by Ruth Nanda Anshen in order to explore the new consciousness which marks mankind's recently acquired ability to tinker with the evolutionary processes of nature. Our unfolding knowledge of the cosmos traditionally places cosmologists in the role of passive observers acquiescing in the thrill of new astronomical explorations of the frontiers of the Universe. Unlike most natural scientists, astronomers cannot perform controlled experiments in a warm laboratory; rather they take whatever the Universe has to offer.

One might think that such a discipline would have little in common with philosophers who concern themselves with the interaction between human beings and their environment. However a current cosmological theme provides a remarkable bridge between the philosophical undertones associated with the origin and fate of the Universe and the human perspective. This is the anthropic principle, according to which the properties of the Universe are determined by our presence as observers. Conditions must be congenial for intelligent life to evolve. This means, for example, that the early Universe could not have been highly irregular, inhomogeneous or chaotic, nor however could it have been perfectly regular, otherwise galaxies

and stars would not have formed. The anthropic principle accounts for the various large-number coincidences involving powers of 10<sup>40</sup>, the ratio of electromagnetic to gravitational coupling constants. These include the mass of a star and the mass of the observable Universe, as well as the coincidence between nuclear, stellar and Hubble expansion time-scales. It even purports to account for the approximate values of the constants of nature: if they differed significantly from observed values, human beings could not have evolved.

Where does this leave us? The uniqueness of our Universe can be attributed to our existence as observers, if we accept the anthropic principle. But have we really advanced our understanding of any aspects of cosmology? In 1925, A.N. Whitehead perceived about cosmology that "there is no parting from your own shadow". Is the Universe merely our shadow? Or perhaps the cosmologists are deceiving themselves and the roles are reversed. The truth may very well be that with only one Universe to explore, we can never resolve this paradox.

Joseph Silk is Professor of Astronomy at the University of California, Berkeley, and author of The Big Bang (W.H. Freeman, 1980).

## All around our star

David W. Hughes

The New Solar System. Edited by J. Kelly Beatty, Brian O'Leary and Andrew Chaikin. Pp.224. ISBN 0-521-23881-1. (Cambridge University Press: 1981.) £9.95, \$19.95. Orbiting the Sun: Planets and Satellites of the Solar System. By Fred L. Whipple. Pp.338. ISBN 0-674-64125-6. (Harvard University Press: 1981.) \$20, £14. Daytime Star: The Story of Our Sun. By Simon Mitton. Pp.191. ISBN US 0-684-16840-5; ISBN UK 0-571-11659-0. (Charles Scribner's Sons/Faber & Faber: 1981.) \$14.95, £10.

WE LIVE in the Solar System. Our planet, Earth, orbits the Sun and the theme of these three books seems to be that the more we know of such bodies the better. In effect we are presented with a progress report. Governments have spent large amounts of money on investigating our neighbouring planets and star. What have we got from it? Where do we go next? Why bother doing more? The books under review try to answer these questions.

The investigation of the Solar System has passed through three phases. The classical period encompassed the works of scientists such as Galileo, Copernicus, Kepler and Newton. This was a time of discovery and astronomy was almost entirely concerned with the planets, stars being

R420

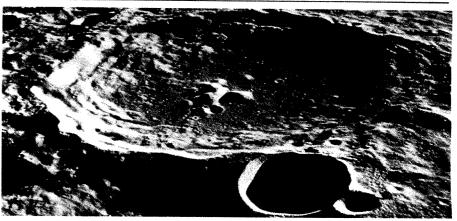

fixed points of light of little known significance. The second phase started in the late 1800s when astrophotography and spectroscopy spawned the discipline of astrophysics. During this period planetary investigation degenerated into a Cinderella science. The early 1960s saw the dawn of planetology. Since then spacecraft have been flung round, onto and into all of the planets known to the ancients, producing a veritable explosion of knowledge.

The first book under review is The New Solar System. Very rarely does one come across such an excellent account; I feel honoured to have a first edition as it is bound to run to many printings. The editors have collected together 20 chapters. each of about ten pages, written by a roll call of American scientists which reads like a Who's Who of US planetology. It is invidious to omit names, but as an indication of the standard it includes Eddy on the Sun, Chapman on asteroids, Burns on planetary rings, Wood on meteorites, Masursky on Mars, Shoemaker on the role of fragmentation and so on. The book concentrates on the comparative approach. It is much easier to discuss the surfaces of the terrestrial planets (Mercury, Venus, Earth and Mars) in one chapter and, for example, their atmospheres in another than to have an isolationist attitude to individual planets

The joy of reading the book is greatly enhanced by the illustrations. Not only does it bulge with space photographs, but it also contains a collection of coloured illustrations by artists Charles Wheeler, Don Davies and Jon Lomberg.

The editor's aim was to provide a book about the third phase of planetary exploration, the space-age planets, a book which would make enjoyable reading for those with either a professional or a casual interest. They have succeeded admirably. The fact that the publishers have produced this large format, beautifully illustrated, quality book at less than £10 is verging on the miraculous. I advise all readers to buy it

The second book is Fred Whipple's Orbiting the Sun: Planets and Satellites of the Solar System. This is a completely revised and updated edition of Whipple's classic text, Earth, Moon and Planets, which was first published in 1941. Whipple is Philips Professor of Astronomy, Emeritus, at Harvard University and Senior Scientist, Emeritus, at the Smithsonian Institution Astrophysical Observatory. He has devoted his life to the study of astronomy and space science, especially meteors, comets, space exploration planning, satellite tracking, novae and supernovae, Solar System evolution and practical astronomy; it is fascinating to read the view of such a man about the place of Earth and Moon within the planetary context. Whipple writes for the general reader and mathematics are avoided; however, the book does present the basic foundation of planetary astronomy and

The crater Daedalus on the far side of the Moon, photographed by Armstrong and Aldrin on July 21, 1969. The picture is taken from *The Atlas of the Universe* by Patrick Moore, a new edition of which has just been published by Mitchell Beazley, price £19.95.

does stress the underlying scientific principles. The author has also managed to integrate the three phases of Solar System investigation and we realize that all still have a role to play. We might move from bleary telescope images to the eye-opening, crisp detail of the space probe, but the Earth-based telescopes have recently revealed Pluto's moon, the rings of Uranus and Apollo asteroids. Also we realize that stars and planets are not to be compartmentalized. Whipple leaves us in no doubt that the origins and deaths of stars are intricately connected with the origin and evolution of our planetary system. The book is well written, well illustrated, well worth reading and a worthy successor to the previous editions.

My final book is *Daytime Star: the Story of Our Sun* by Simon Mitton. The word "Story" in the title describes the book well — Mitton dives into the subject and returns with a net bulging with intrigues. Why did ancient man worship the Sun and build stone circles to track its path? What drives the sunspots? Does the solar energy output vary slightly and thus trigger ice ages? What do neutrinos tell us about the solar interior? What have we learnt from space

about the solar atmosphere? Mitton has a racy style and we find atomic particles sloshing, neutrons bashing, gases toasting and gravity crunching.

There is much to be learnt about the Sun from this book, and it fills a definite gap in the astronomical library of the general reader. The author worried me when he stated that in 1964 "the finding of the solar wind was a result of astronomical observations of extremely remote radio sources" but 86 pages later he changes his mind and Biermann's 1951-1953 observations of comet tail phenomena are given the credit. I also found that the position of the Sun in the stellar hierarchy needed much more emphasis and that it is not enough just to say that the Sun has "an average size, typical mass, normal structure, temperature and luminosity". Granted the Sun is on the Main Sequence but it is also about nine times more massive than the average star and about 2,000 times more luminous. But these are minor quibbles about a book which is generally of a high standard and is definitely a good read.

David W. Hughes is a Lecturer in Astronomy and Physics at the University of Sheffield.

# The philosophy of astronomical discovery

David S. Evans

Cosmic Discovery: The Search, Scope, and Heritage of Astronomy. By Martin Harwit. Pp.334. ISBN UK 0-7108-0089-4; ISBN US 0-465-01428-3. (Harvester Press, Brighton/Basic Books, New York: 1981.) £12.95, \$25.

In the blurb Sir Fred Hoyle describes Cosmic Discovery as "A remarkable book. A unique book". So it is. It is an examination of the epistemology of astronomy, and one of those books which will set astronomers and philosophers thinking and talking. It is not a book which will command general acquiescence. Exactly how much influence it will have is hard to

say since it is certainly not everybody's cup of tea.

It starts off, oddly enough, with an idea connected with the collection of baseball cards. If one finds a duplicate, the set must be finite and if at any stage one counts up the number of single different cards (A) and the number of duplicates (B) the size of the set (n) may be estimated from the statistical formula n = A(A+2B)/2B. Harwit then applies this to astronomical discoveries of which he considers there are 43 distinct ones, and of these seven are recognized in two different ways. He is very careful about defining what he means by different ways, that is by totally unrelated

# **REIDEL'S AUTUMN LIST**

#### Cosmic Plasma

H. ALFVÉN

A new and refreshing approach to cosmic plasmas by this Nobel Prize winner. Alfvén shows how recent electric current descriptions have changed our views of magnetospheric plasma and how laboratory plasma results have been translated to space with impressive consequences. An ideal text.

176 pp. Cloth Dfl. 75,— / US \$ 39.50 ISBN 90-277-1151-8

# Photometric and Spectroscopic Binary Systems

E. B. CARLING and Z. KOPAL (eds.) A collection of papers offering a detailed discussion of binary stars and contemporary methods of observation. Recent photometric techniques with light-curve analysis, photoelectric observations, and spectroscopic observations are the main topics.

583 pp. Cloth Dfl. 135,- / US \$ 69.50 ISBN 90-277-1281-6

# Fifty Years of Electron Diffraction

P. GOODMAN (ed.)

This important publication by the International Union of Crystallography is the first history and current status report of a rapidly growing subject. Liberally illustrated, the volume incorporates a detailed literature survey. 446 pp. Cloth Dfl. 155,— / US \$ 75.00 ISBN 90-277-1246-8 Paper Dfl. 80,— / US \$ 39.50 ISBN 90-277-1331-6

# The Orion Complex: A Case Study of Interstellar Matter

C. GOUDIS

A useful compilation of the current observational material (both data and observational methods) on the Orion complex, providing a reference manual for the specialist which will also serve as an introduction for the newcomer. approx. 472 pp.

Cloth approx. Dfl. 140,— / US \$ 59.50 ISBN 90-277-1298-0

#### **Physical Processes in Red Giants**

I. IBEN, JR. and A. RENZINI (eds.) A collection of papers by the world's experts on the physical processes in red giants, one of the most dramatic periods in a star's life. The interrelatedness of the various processes is emphasised, and future problems are clearly defined.

503 pp. Cloth Dfl. 125,- / US \$ 66.00 ISBN 90-277-1284-0

#### Investigating the Universe

F. D. KAHN (ed.)

A collection of papers by past and present members of the Manchester University Astronomy Department on the occasion of Zdeněk Kopal's retirement; contributions deal with Objects with High-Speed Flows, Close Binary Systems, Celestial Mechanics, and the Solar System.

approx. 448 pp. Cloth Dfl. 125,-- / US \$ 54.50 ISBN 90-277-1325-1

# Relation between Laboratory and Space Plasmas

H. KIKUCHI (ed.)

These proceedings highlight the communality of basic plasma phenomena, and point out similarities and differences observed in the laboratory and in space. A book that will interest astrophysicists, laboratory plasma researchers, geophysicists and others. 426 pp. Cloth Dfl. 110,—/US \$ 58.00 ISBN 90-277-1248-4

# The Impact of Modern Scientific Ideas on Society

C. M. KINNON, J. G. RICHARDSON, and A. N. KHOLODILIN (eds.)

This volume, as well as highlighting Einstein's scientific contributions on the occasion of the hundredth anniversary of his birth, examines the overwhelming influence of science on modern life and the ensuing responsibilities for scientists.

217 pp. Cloth Dfl. 50,- / US \$ 26.50 ISBN 90-277-1238-7

#### Comets and the Origins of Life

C. PONNAMPERUMA (ed.)

This volume addresses the important question, 'Have comets made a contribution to the origin of life on earth?'. The papers draw on current astronomical and chemical knowledge of comets and delve into the theoretical claims made about them.

289 pp. Cloth Dfl. 85,-- / US \$ 39.50 ISBN 90-277-1318-9

# Is Science Sexist? And Other Problems in the Biomedical Sciences

M. RUSE

Ruse brings together in this book a number of recent essays on overheated issues in the biomedical sciences. He ranges from evolutionary theory and sexual theory to sociobiology and genetic counselling, posing the controversial questions, "Is Science Sexist?" and 'Are Homosexuals Sick?' 320 pp. Cloth Dfl. 80,— / US \$ 42.00

320 pp. Cloth Dfl. 80,- / US \$ 42.00 ISBN 90-277-1249-2

Paper Dfl. 32,50 / US \$ 14.95 ISBN 90-277-1250-6

# Pulsars - 13 Years of Research on Neutron Stars

W. SIEBER and R. WIELEBINSKI (eds.)

Provides a long overdue assessment of this topical field of astronomy; an extensive review of the data gathering, interpretation, and theory on pulsars over the past 13 years.

491 pp. Cloth Dfl. 115,- / US \$ 60.50 ISBN 90-277-1280-8

Paper Dfl. 55,- / US \$ 28.95 ISBN 90-277-1282-4

# The Land of Stevin and Huygens D. J. STRUIK

A lively social history of the monumental scientific and engineering advances in Holland during the celebrated Golden Age of the Dutch Republic, against the backdrop of the social, religious and philosophical movements of the era.

182 pp. Cloth Dfl. 80,-- / US \$ 39,50 ISBN 90-277-1236-0

Paper Dfl. 40,— / US \$ 19.50 ISBN 90-277-1237-9

#### **Stellar Paths**

P. VAN DE KAMP

This book provides both an historical perspective and the current 'state of the art' on studying stellar paths on a background of distant reference stars. The dramatic improvements in accuracy with new long-focus instruments are fully described.

171 pp. Cloth Dfl. 70,-- / US \$ 34.95 ISBN 90-277-1256-5

D. Reidel Publishing Company

P.O. Box 17, 3300 AA Dordrecht, Holland 190 Old Derby St., Hingham, MA 02043, U.S.A.

# THE LANGUAGE OF SCIENCE

#### **MOLECULAR BIOLOGY,** PATHOGENICITY, AND ECOLOGY OF **BACTERIAL PLASMIDS**

edited by Stuart B. Levy

Tufts University School of Medicine

**Royston C. Clowes** 

The University of Texas at Dallas

and Ellen L. Koenig

Pedro Henriquez Urena University, Dominican Republic

A comprehensive examination of naturally occurring plasmids and those created in the laboratory. Progress in recombinant DNA uses of plasmids is summarized, along with future possibilities for this research. Details the pathogenic traits encoded by plasmids in the pathogenesis of disease, and the ecologic ramifications of introducing plasmid-bearing bacteria into an environment to clean up toxic materials. 720 pp., illus., 1981, \$59.50

#### FERTILIZATION AND EMBRYONIC **DEVELOPMENT IN VITRO**

edited by Luigi Mastrolanni, Jr. University of Pennsylvania and John D. Biggers

This book presents up-to-date and comprehensive coverage of the techniques used in in vitro fertilization, embryo culture, and embryo transfer. Covering processes that have been applied to both animal breeding and treatment of reproductive disorders, the authors examine development and differentiation at cellular and molecular levels, the study and treatment of infertility in women and domestic animals, and other topics. 375 pp., illus., 1981, \$45.00

#### NEUROENDOCRINOLOGY OF REPRODUCTION

Physiology and Behavior edited by Norman T. Adler

University of Pennsylvania

.. outstandingly good and timely—clearly written, well illustrated, thorough, authoritative, and by a stellar group of neuroendocrinologists. Excellent bibliographies. By far the best coverage available in this rapidly expanding -Charles H. Sawyer, University of California

at Los Angeles Medical School

592 pp., illus., 1981, \$42.00 paperback text: \$18.95

#### **ENVIRONMENTAL EFFECTS OF** OFFSHORE OIL PRODUCTION

The Buccaneer Gas and Oil Field Study

edited by Brian S. Middleditch

University of Houston

Uniting the findings of nearly 30 individual research groups from a five-year comprehensive research project in one source, this timely volume assesses the ecological effects of offshore production activities. Volume 14 in the Marine Science series, coordinating editor, Ronald J. Gibbs. 464 pp., illus., 1981, \$49.50

233 Spring Street, New York, N.Y. 10013

#### CANCER

**A Comprehensive Treatise** 

Volume 1 (Second Edition)

#### **ETIOLOGY**

#### **Chemical and Physical Carcinogenesis** edited by Frederick F. Becker

M.D. Anderson Hospital and Tumor Institute, Houston

Examining the various components involved in the development of cancer cells, the second edition of Cancer (Volume 1) presents reports of new advances in the number of fields that address areas such as the nature and specificity of intracellular macromolecular interactions and the sequences of cellular alteration required for the development of the carcinogenic process. approx. 700 pp., illus., 1982, \$69.50

#### **IMMUNOLOGIC DEFECTS IN LABORATORY ANIMALS 1 & 2**

edited by M. Eric Gershwin

University of California School of Medicine, Davis and Bruce Merchant

Food and Drug Administration, Maryland

in two volumes

Emphasizes genetic, anatomic, pathologic, and functional aspects of immune defects and their conceptual and theoretical relationships. Also contains practical information regarding the study of immune disorders, including the freezing of mammalian embryos.

**Volume 1:** 380 pp., illus., 1981, \$37.50 **Volume 2:** 402 pp., illus., 1981, \$42.50

two volume set: \$72.50

#### **CELL BIOLOGY OF EXTRACELLULAR MATRIX**

edited by Elizabeth D. Hay

Harvard Medical School

This book makes a compelling case for the relevance of the extracellular matrix to cell biology. Cell Biology of Extracellular Matrix presents the state of the art of this area in an engaging style, providing ample citations of more technical and historical reviews, and many electron micrographs and diagrams, approx. 425 pp., illus., 1981,

text adoption price on six or more copies: \$24.50

#### OCEANOGRAPHY FROM SPACE

edited by J. F. R. Gower

Institute of Ocean Sciences, Patricia Bay, Sidney, British Columbia

Gives a comprehensive review of the techniques now available for studying the oceans from space. Includes a wide variety of applications. Among the topics: satellite altimetry, the remote sensing of ice, passive microwave observations, radar studies of the sea surface, and water color measurements. Volume 13 in the Marine Science series. 998 pp., illus., 1981, \$95.00

#### JOURNAL OF BIOENERGETICS AND BIOMEMBRANES

edited by **D. Rao Sanadi** 

Boston Biomedical Research Institute

Features publication of research papers and short review articles related to the structure and function of biological membranes, including energy transduction in mitochondria, chloroplasts, and bacterial membranes. Also covers transport, regulation, hormone action, excitable membranes, muscle function, pinocytosis, and membrane fusion.

Subscription: Volume 14, 1982 (6 issues) \$57.00

techniques, perhaps best illustrated by the fact that the existence of galaxies was recognized by optical observations, but would now independently be found from radio observations. Putting A = 35, B = 7in 1979, with one triply recognized phenomenon (C=1), he estimates that there are 123 separate cosmic phenomena to be found of which we have now recognized 35 per cent. From a discussion of the rate of discovery he thinks we might know all of them by 2150 AD, a somewhat depressing conclusion for those who love observational astronomy, though favourable error bars would increase the numbers and postpone the date. Harwit distinguishes between original discoveries and their development, so that our successors may not all be unemployed by then.

He builds upon a figure published by Halton Arp in 1965 which defines the limitations of observations of extended visual sources considered in terms of their absolute magnitudes and linear diameters. In an elaborate analysis of techniques he considers the parameters of possible detection methods — frequency, size, spectral resolution, time resolution, ellipticity of polarization and intensity — and constructs multidimensional phase diagrams to show what is now accessible and what might become accessible in the future, and classifies each of his fundamental discoveries according to this scheme.

One chapter outlines his selected set of phenomena and the circumstances of their discovery. He makes a number of points in passing — for example that new discoveries follow the introduction of new techniques, with which few readers will quarrel. However he tends to think only of revolutions in techniques rather than in their availability. To an observer one of the most important events of the past few decades was the identification by Thackeray and Wesselink of both Cepheids and RR Lyrae stars in the Magellanic Clouds because of the newly available 74-inch reflector in the Southern Hemisphere. The resultant doubling of the scale of the Universe does not rank in his list of 43 discoveries. He mentions the serendipity of many discoveries, but fails to mention the outstanding discovery by John B. Irwin that S Normae was a member of the cluster NGC 6087. In fact his accounts of pulsating variables and flare stars leave a good deal to be desired and he fails to mention that pulsations continue down even into the white dwarf range. Indeed, one has the impression that in his accounts of fundamental discoveries Harwit confines himself to data from a rather restricted selection of well-known sources, especially those closest to the NASA publicity machine. For example, in his remarks on pulsars we fail to find any mention of the names of Cocke, Disney, Taylor, Nather or Warner, and the name of Lundmark is omitted from the story of the identification of the 1054 AD supernova remnant. The independent observation of

the Uranus rings by Joseph Churms gets no mention. Among other distinguished absentees, de Vaucouleurs rates no inclusion for the discovery of the local supergalaxy.

Though one can quarrel with Harwit's selection of phenomena and his historical accounts, perhaps this will not invalidate his main thesis for some readers. He remarks that many of the discoverers were not originally trained as astronomers, which is true but easily explained. The basic discoveries in radio, X-ray or gamma-ray astronomy were made before anybody could describe himself as an astronomer specializing in these fields. Until a few decades ago, employment opportunities in astronomy were so few that even aspirant astronomers took care to have an employable skill in some other field as a hedge against failure in the discipline of first choice. He remarks that by his reckoning the major proportion of recent discoveries has been made by Americans. though he might have added that even now a high proportion of top posts in American astronomy are held by individuals whose original training was received elsewhere, apparently himself included.

Lastly, he notes that many of the most original discoveries have been made by individuals outside the main stream of astronomical organization and funding. This, of course, has been remarked in other sciences; one can command organized research but it seems impossible to command true originality. However, insofar as observational astronomers in all fields are now married to large and expensive instruments, detailed planning and allocation of resources is essential.

The last part of the book contains Harwit's message - "How should we organize astronomy?". He argues for 13 recommendations, many of which are obvious enough - better training in physics and mid-career training in new techniques for astronomers, and vigorous introduction of exponents of new techniques in astronomy. Long-term grants will better allow astronomers to address fundamental problems and the current peer review system must be loosened up to encourage true innovation, "which can seldom be justified in advance". On the other hand, projects should not be kept on just because they have gone on for a long time. He wishes to encourage gravitational wave and neutrino astronomy and believes that in the electromagnetic domain current observing capabilities could be increased by a factor of 1,000 at modest cost. He finishes with a plea for policy to be set by panels of generalists of "unusual breadth of interest and far-ranging vision", more frequent policy reviews and frequent analyses of the factors which contribute to astronomical success.

These are fine words, but how to implement them in the real world with limited funds for pure research is another matter. In view of Harwit's desire to have more

frequent review committees, it is odd that he admits that "there is no evidence . . . that astronomical planning committees have in any way advanced the rate at which new astronomical phenomena are discovered . . . ". This is the paradox: astronomers need to spend a lot of money, much from public sources, and need to be accountable. They can guarantee the addition of large amounts of extremely valuable knowledge from their efforts. But the history of science demonstrates two things. One is that those who have predicted the exhaustion of the results of research have usually been proven wrong, however logical their arguments. The other is that discoveries of real originality are most often made by people who ignore the basic plan and pursue their own hunches. Many of them are rightly written off as cranks, but those who succeed are geniuses.

David S. Evans is a former Associate Director for Research at the McDonald Observatory and currently a Professor of Astronomy at the University of Texas at Austin.

## Relativity for all

D.J. Raine

Discovering Relativity for Yourself. By Sam Lilley. Pp.425. ISBN hbk 0-521-23038-1; ISBN pbk 0-521-29780-X. (Cambridge University Press: 1981.) Hbk £17.50, \$49.50; pbk £7.95, \$19.95.

ONE approach to physical science for the intelligent but innumerate layman is through analogy and example, omitting the why and wherefore. Sam Lilley has a different approach. He believes that students can be taught how to work things out for themselves.

Schopenhauer opined that mathematical truths properly presented can, in any case, be grasped intuitively, thereby circumventing the aridity of the Euclidean mode, for which he gave as sole justification a pictogram proof of Pythagoras's theorem. Lilley has a beautiful extension of this to the invariance of the interval in special relativity. But, even when only elementary mathematics is involved, not everything can be presented so easily; for example, on p.74 we must digress from space-time diagrams to explain negative numbers.

With general relativity the difficulties multiply. The equivalence principle is

The latest edition of *The Milky Way* by Bart and Priscilla Bok has just been published by Harvard University Press. The book, which first appeared in 1941 and has now been revised for the fifth time, costs £14.

discussed well in terms of accelerated observers in special relativity. But to master Lilley's ''near equations'' seems to require as much effort as would elementary calculus proper. Some limitations of the approach are apparent from the author's speculations on an alternative theory. This is incompatible with the precession of Mercury, but the reader (or author) is not provided with the confidence to do the relevant short calculation. Nor does one get any feeling for the results of the theory in cosmology, black holes or gravitational waves.

There are some mistakes: for example, a too-simple proof that bodies cannot move with the speed of light, and a peculiar notion of covariant tensors, which arises from confusing two meanings of "covariant". And amongst the more serious errors, two incompatible equations for the same gravitational force arise from an inconsistent approximation.

But for me the achievement outweighs these flaws of execution. Of the greatest importance is the demonstration, through a large number of well-made teaching points, that mathematics, the language of science, is available to anyone with sufficient motivation and the right guide.

D.J. Raine is a Lecturer in Theoretical Astrophysics at the University of Leicester. His books include Einstein and Relativity (Priory Press, 1975) and The Isotropic Universe (Adam Hilger, 1981).

R.V. Jones

James Clerk Maxwell: A Biography. By Ivan Tolstoy. Pp.194. ISBN 0-86241-010-X. (Canongate, Edinburgh: 1981.) £9.95.

FOR many years there hung in one of the corridors of the Electrical Laboratory at Oxford a photographic portrait of someone whom none of the staff could identify. Presumably it had been placed there by the Professor of Physics, J.S.E. Townsend; but after his death, the identity of the portrait was forgotten. It was, in fact, of James Clerk Maxwell.

Maxwell has been almost as little known in his native Scotland, where his memory has been heavily overshadowed by that of - and this despite the fact that Einstein himself credited Maxwell with having brought about the greatest revolution in physics since the time of Newton. Not only did Maxwell create the electromagnetic theory which led to the discovery of radio waves and of electromagnetic radiation pressure, but he also formulated his distribution law governing the molecular velocities in gases, the basis of automatic control theory and the principles of kinematic design; and he demonstrated the first colour photograph.

The current year has seen the one hundred and fiftieth anniversary of his birth on 13 June 1831, while less than two years ago there occurred the centenary of his death. The commemoration of these anniversaries has coincided with increasingly wide-spread recognition of his tremendous contributions, and with papers and books describing aspects of his life and work, notably C.W.F. Everitt's short but carefully written biography (Charles Scribner's Sons, 1975) and the exhibition of Maxwell memorabilia at last year's Royal Society conversazione.

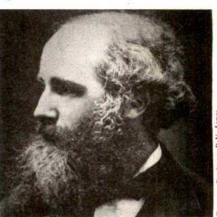

Now we are presented with another short and very readable biography, by Ivan Tolstoy, who in his preface sets out his objective:

For physicists the name of James Clerk Maxwell ranks next to Newton and Einstein. Yet among non-scientific people Maxwell's image is surprisingly faint. It is hoped the present book will help remedy that injustice. This pretends neither to be a definitive biography, nor a work of historical scholarship. It is, rather, a book for the lay reader.

Even so, and although the author has, as he says, drawn largely on secondary sources, more specialist readers will find that he has thrown shafts of light on Maxwell's character and methods of working. And in well-drawn quotations from Maxwell's own writings he has followed one of his subject's own precepts:

It is a great advantage to the student of any subject to read the original memoirs of that subject, for science is always most completely assimilated in the nascent state.

One of the rare points in the book which could be questioned concerns the process by which Maxwell came to conceive the famous displacement current in a vacuum. Tolstoy says that "There could be no physical or logical justification for keeping the concept in the context of a vacuum" This might be true if Maxwell regarded a vacuum as containing absolutely nothing, but in his 1864 paper he stated his belief in "an aethereal medium filling space" and in its having a "small but real density"; and he evidently retained this view throughout his work, for towards the end of the Treatise of 1873 he repeated "We must therefore regard the medium as having a finite density" (para.782). So Maxwell's train of thought was both physical and logical.

James Clerk Maxwell, the portrait that hung in the Electrical Laboratory at Oxford.

Tolstoy remarks elsewhere that "Both Einstein and Maxwell were stronger in physical intuition than in mathematics" which struck an immediate resonance in my memory with something Einstein said in conversation with F.A. Lindemann during his visit to Oxford in 1931. He was commenting on the popular description of himself as a mathematician: "I am not a mathematician. I am a physicist — if I had been a mathematician I could not have done what I have". But, of course, both Einstein and Maxwell had an impressive command of mathematics when they needed it, and Maxwell was outstandingly strong in geometrical reasoning.

Tolstoy's short account is both penetrating and sympathetic regarding Maxwell's personal relationships, of which it gives a warmly human picture; and it contains many thoughtful comments on Maxwell's physics and the context in which his advances were made. It is a book well worth reading.

R.V. Jones is Professor in the Department of Natural Philosophy at the University of Aberdeen, and author of The Complete Physicist: James Clerk Maxwell 1831–1879 (Yearbook of the Royal Society of Edinburgh, 5–23; 1980).

# THEORY OF PHASE TRANSITIONS: Rigorous Results

Ya G SINAI, Academy of Sciences of the USSR, Moscow

This outstanding new work brings together Professor Sinai's own important results with the recent brilliant work by Fröhlich, Simon and Spencer (on the existence of order in the classical Heisenberg model) and an account of continuous symmetries in lattice gauge models.

Every fact is set forth with such clarity and completeness that the reader can grasp the major problems of various topics in the theory of phase transitions.

The author has an almost legendary reputation in the field of exact results in statistical mechanics, particularly in ergodicity problems. Any book by him will therefore be required reading for all postgraduate and working theoretical physicists,

# **Antennas in Matter**

Fundamentals, Theory & Applications by Ronold W. P. King & Glenn S. Smith

with contributions by Margaret Owens and Tai Tsun Wu

Antennas in Matter provides an introduction to and a comprehensive description of the properties of antennas and probes embedded within or near material bodies such as the earth, the ocean, or a living organism. It presents a full treatment of a sequence of research that has become increasingly important in recent years: the use of underground antennas for communication with miners and subway trains, and for the geophysical exploration of the earth's crust; underwater antennas for communication with and between submarines and divers, and for oceanic research including telemetry from areas beneath the polar icecaps; and antennas embedded in or near living organisms for biomedical telemetry and diagnostics in tissue and layered media with electromagnetic properties as diverse as those of fat, muscle and bone. 784 pages, March 1981, £52.50.

# The Photic Field

Parry Moon & Domina Eberle Spencer

The Photic Field brings a formal elegance and completeness to the portion of geometrical optics that deals with amounts of radiant energy. Since the time of Lambert, this discipline has been handled piecemeal by a great variety of methods but, by utilizing the full potentialities of field theory, the book unifies the subject and forges a powerful tool for handling practical applications. As the title emphasizes, the authors' approach is based on geometrical optics (photons) rather than physical optics (waves).

240 pages, September 81, £17.50.

# **Evolution of Physical Oceanography**

Scientific Surveys in Honor of Henry Stommel edited by Bruce A. Warren and Carl Wunsch

This book opens with five brief essays offering personal reminiscences of Henry Stommel and assessments of his scientific contributions. It then presents 18 invited survey articles grouped into four sections: General Ocean Circulation; Physical Processes in Oceanography; Techniques of Investigation; and Ocean and Atmosphere.

"While Stommel has dealt with each of these areas in his work, the rest of us content ourselves with one, or at best maybe two, of these subdivisions of physical oceanography. Perhaps this is why the book is so important". Arnold L. Gordon, Deep-Sea Research.

## Where is everybody? Some new answers

Gerard K. O'Neill

Are We Alone? The Possibility of Extraterrestrial Civilizations. By Robert T. Rood and James S. Trefil. Pp.262. ISBN 0-684-16826-X. (Charles Scribner's Sons: 1981.) \$14.95.

Is the origin of life so extraordinarily improbable an event that it has occurred but once in the history of our galaxy, or do star-systems other than our own teem with intelligent life, able to communicate with us? Surely this question, raised almost 40 years ago by Enrico Fermi, is one of the most profound that we can imagine.

In an engaging and readable book, Rood and Trefil outline an emerging modern view of the answer. Their style is informal and unpretentious, and the level is suitable for interested non-scientists, but they offer tid-bits of detail for specialists. Given the provocative and necessarily speculative nature of their subject-matter, it seems a happy choice on their part, as well as an honest one, that they include a chapter listing their own divergences of opinion and the arguments made on either side of the issues.

They begin with the seminal paper, "Searching for Interstellar Communications", by Giuseppe Cocconi and Philip Morrison, which appeared in Nature in 1959 (184, 844-846). There the authors pointed out that sensitive radio receivers could detect signals from transmitters of moderate power over interstellar distances. Frank Drake, already thinking along similar lines, was further stimulated by Cocconi and Morrison's paper and carried out Project Ozma, using a radiotelescope to listen for possible artificial signals emitted from the nearby, solar-type Tau Ceti and Epsilon Eridani systems. Although no recognizably artificial interstellar signals were ever detected, then or in searches over the succeeding decades, there grew in the early 1960s something of a consensus among those scientists interested in the question. It was based on the assumptions they made of probabilities: that a star will have planets, that life will develop on one such planet, that it will develop technological expertise and that a culture capable of communication will survive long enough to be heard. Those probabilities and a few other factors, simply multiplied together, form what is variously called the Sagan-Drake, the Drake or the Green Bank Equation. Rood and Trefil choose the last version, as a memorial to the first scientific conference (1961) on interstellar communication. The participants at the Green Bank conference concluded that intelligent life was abundant in our galaxy, that physical space-travel over interstellar distances would be forever impractical and that communication could occur only by radio transmissions; the only problem was to find the right frequency and the signal code.

One definite signal, unmistakably intelligent and extraterrestrial, could end the argument at any time, but until that happens everyone can speculate. Most of Are We Alone? is devoted to the fascinating skein of logic woven over the past ten years by a younger generation of scientists, who have reached a fairly general agreement among themselves that the Green Bank participants were both too sanguine on their probabilities and too short-sighted on technical progress. In the modern view, life is a far more unlikely phenomenon than had once been thought, and there is a strong possibility that it is unique to our planet.

Michael Hart stimulated much of the new research on the Fermi question, and the authors discuss Hart's work in considerable detail. Dr Hart, now at Trinity College in Texas, set up a mathematical model of the Earth's atmosphere, and in 1978 traced the evolution of that atmosphere by computer over geological time, from its formation by volcano emissions to its complete transformation through biochemical processes once life had formed. Hart found that the survival and evolution of life depended on an extraordinarily lucky series of accidents, by which the temperature of the Earth remained remarkably constant for most of the age of our planet. Had we not been so fortunate as to be located at precisely the right distance from the Sun, within margins of no more than one or two per cent, Earth would now be as lifeless as Mars or Venus, according to Hart's calculations.

The young revolutionaries further conclude that their elders were badly

The opening lines of the seminal paper by Cocconi and Morrison (1959) which stimulated others to listen for signals from space.

No theories yet exist which enable a reliable estimate of the probabilities of (1) planet formation; (2) origin of life; (3) evolution of societies possessing advanced scientific capabilities. In the absence of such theories, our environment suggests that stars of the main sequence with a lifetime of many billions of years can possess planets, that of a small set of such planets two (Earth and very probably Mars) support life, that life on one such planet includes a society recently capable of considerable scientific investigation. The lifetime of such societies is not known; but it seems unwarranted to deny that among such societies some might maintain themselves for times very long compared to the time of human history, perhaps for times comparable with geological time. It follows, then, that near some star rather like the Sun there are civilizations with scientific interests and with technical possibilities much greater than those now available to us.

misled by (in my phrase) "temporal chauvinism", a lack of appreciation of the probable development of technology beyond our era. If there is a civilization more advanced than our own, it will be ahead not just by decades but by millenia - and with technology to match. The authors conclude that the modern concept of space colonies, not published until more than a decade after the Green Bank conference, logically confounds many of the assumptions made at the time. Space colonies, they estimate, are certainly feasible technically, do not require a particularly high level of technology, and have such extraordinarily high survival value for any civilization reaching its nuclear age that they will inevitably be developed by any long-lived civilization capable of interstellar radio communication. Given the certainty of space colonies, virtually every star-system is a hospitable target for colonization by any species, no matter what its point of origin or requirements of temperature, gravity and atmosphere.

The development of space colonies therefore means, in the opinion of the young scientists of the modern school, that physical interstellar travel, first by robot probes and then by living colonists, is a natural and not particularly difficult stage in the development of any intelligent civilization. That conclusion is made quantitative by computer simulations carried out by Eric M. Jones at the Los Alamos Scientific Laboratory. Dr Jones comes to a single conclusion, remarkably insensitive to assumptions about ship speeds, the gestation time for a civilization around a star before it spawns colonies to move on to other stars, and other variables. He finds that the spread of a civilization outward across the entire galaxy takes no more than at most a few thousandths of the galactic age — that is, the expansion is explosive. My own calculations confirm that conclusion, and suggest an even shorter expansion time, less than one tenthousandth of the galactic age. I argue that the outward movement of self-replicating robot probes is more certain than that of life, but Jones may well be right in his assertion that, in our own case, "The human migrants will not be far behind the probes".

In the view of the young revolutionaries, based on that chain of logic, if there had ever been an intelligent race prior to our own its descendants would be here already. And as we seem to have evolved locally, we are not they. Hence, there's a strong probability that we are in fact alone in our galaxy. It is thought-provoking that Enrico Fermi, by his famous question "Where is everybody?" appears to have arrived at the same conclusion 40 years earlier.

Gerard K. O'Neill is Professor of Physics at Princeton University and President of the Space Studies Institute. His new book 2081 (Simon and Schuster/Jonathan Cape; 1981) explores the impact of technology on the human prospect.

# Snow: reflections on physics in our time

H.B.G. Casimir

The Physicists: A Generation that Changed the World. By C.P. Snow. Pp.192. ISBN UK 0-333-3228-2; ISBN US 0-316-80221-2. (Macmillan, London/ Little, Brown: 1981.) £8.95, \$15.95.

ALTHOUGH physicists like to insist that they are anything but narrow-minded specialists, only few of us have been professionally successful outside the field of science. C.P. Snow was one such rara avis. After an honourable career at Cambridge as a research fellow and later as a tutor at Christ's College, he became famous as a novelist and, moreover, distinguished himself as a Civil Service Commissioner. In his well-known Rede Lecture of 1959 he stressed the gap between "Two Cultures" but he himself tried to bridge that gap — his novels have given many readers a better understanding of the attitudes and aspirations of academic scientists.

In the present book, the first draft of which was completed just before his death on 1 July 1980, Lord Snow returns to science. In eleven chapters he depicts in broad strokes the stupendous development of physics during our century, tells about the main contributors to that development, explains its decisive influence on human society and dwells on the moral responsibility of scientists. In addition there are three appendices: Snow's farsighted editorial in *Discovery* of September

1939; Einstein's letter to President Roosevelt; and Snow's speech on the moral un-neutrality of science, delivered in 1960 to the American Association for the Advancement of Science. The book is abundantly illustrated with well chosen photographs and diagrams.

Most physicists will agree with the general tenor and with the message of Snow's book. Also, as was to be expected, Snow writes clearly and fluently, and he often succeeds in characterizing a physicist in a few pregnant sentences, for instance Fermi on p.79:

He had been recognized very young as one of the physicists of the century, and the only one who could work on equal terms with the greatest in both theory and experiment. There had been no one like that for generations . . . . If Fermi had been born thirty years earlier, it was possible to imagine him discovering Rutherford's nucleus, and then proceeding to Bohr's theory of the atom. . . . As a professional scientist, not as a cosmic thinker such as Einstein or Bohr, he was one of the very greatest.

William Cooper tells us in his introduction that Snow intended to write mainly from memory and it is clear that the book is not based on careful historical studies. It is a personal narrative, but a personal narrative by a man like Snow is well worth reading. For a physicist it is stimulating to compare Snow's choice and evaluation — often based on close acquaintance with the persons and the

subjects discussed — with one's own views. But a general reader should realize that Snow's presentation is often incomplete and may lead to a one-sided or even distorted picture: it is an interesting but not entirely reliable guide.

There is, for instance, no indication of the important role of kinetic theory and statistical mechanics in the development of the atomic theory of matter; Boltzmann is not mentioned, Gibbs only as the creator of chemical thermodynamics. Einstein's work in this field passes unnoticed also. Yet it was Perrin's experimental confirmation of Einstein's predictions concerning Brownian motion that convinced many unbelievers of the real existence of atoms. Similarly, Einstein's theory of the specific heat of solids at low temperatures convinced many physicists of the reality of quantization. When writing about crystallography and X-rays, Snow mentions W.L. Bragg (Sir Lawrence) and Bernal, but fails to mention Bragg's father (Sir William) and von Laue. Wave mechanics is called the De Broglie-Schrödinger theory; that is fair, but note of the curious fact that both De Broglie and Schrödinger did not accept - or did so only with reluctance - Born's interpretation of the wave function as a probability amplitude should not have been omitted. Snow draws a lively picture of Feynman and sketches his work on quantum electrodynamics. Dyson is also mentioned, Schwinger and Tomonaga are

Sometimes the Cambridge (or more generally the British) point of view does not apply elsewhere. When Snow writes on p.42 "Until the Second World War there was little industrial support for physicists" this may have been true in England but in the United States, in Germany and also in my own country industry employed many physicists, some of them even Nobel Prize winners. Further, at Cambridge spectroscopy was considered to lie outside the main compass of physics. Elsewhere it was felt that Rutherford and his school were pioneering an as yet lonely track, whereas the main action was to be found in the unravelling of spectra, which indeed eventually led to the understanding of the periodic system, to the exclusion principle, to the notion of electronic spin and to the semi-quantitative vector model, thus paving the way for quantum mechanics. It was in the 1930s, after the birth of quantum mechanics, that nuclear physics burst into

The book contains a number of plain errors, which Snow, had he lived, would presumably have corrected, and which a careful editor ought to have noticed. Uhlenbeck (p.113) was not involved in the mission of Goudsmit; the Göttingen Nobel Prize winner James Franck is turned into Josef (p.117) and the index lists both James and the non-existent Josef; A.H. Compton was an American, not a British Nobel Laureate (p.120). It was not Gell-Mann-

Germany in 1933 — students and Nazis burning books by foreign and Jewish authors. The slogan reads "German students march against the un-German intellect". Such scenes led to the flight of Jewish physicists from Germany and eventually to the development of the atomic bomb in the United States.

# **Practical Methods** in Molecular Biology

1981. 49 figures. Approx. 260 pages Cloth DM 69,-; approx. US \$ 32.10 ISBN 3-540-90603-7

The authors offer a valuable opportunity to acquire a clear and useful understanding of DNA technology. Using only procedures that the authors have found consistently reliable, they present a practical guide to contemporary molecular biology. The material covered ranges from basic laboratory techniques to such refined procedures as how to construct, analyze, and use recombinant DNA.

# The Eukaryotic Ribosome

Editor: H. BIELKA

1981. 36 figures, 26 tables. Approx. 320 pages Cloth DM 76,-; approx. US \$ 35.50 ISBN 3-540-11059-3 Distribution rights for all socialist countries: Akademie Verlag, Berlin

The Eukaryotic Ribosome presents the main results obtained thus far while stimulating further experimental studies. The following topics are considered: chemical and physical properties of the macromolecular ribosomal constituents; biosynthesis of ribosomal RNA and proteins, their interactions, localization, and function within ribosomal particles, interactions between ribosomes and membranes; the function of ribosomes in the process of protein biosynthesis and, in this context, nonribosomal components in the mechanism and regulation of translation.

## **International Cell Biology 1980–1981**

Papers Presented at the Second International Congress on Cell Biology, Berlin (West), August 31 – September 5, 1980 Editor: H. G. SCHWEIGER

1981. 595 figures. XVIII, 1033 pages Cloth DM 128,-; approx. US \$ 59.60 ISBN 3-540-10546-8

#### Cell Differentiation

#### Molecular Basis and Problems

Editors: L. NOVER, M. LUCKNER, B. PARTHIER Translated from the German by J. Wieser With contributions by numerous experts

1982. 228 figures, 65 tables. Approx. 670 pages Cloth approx. DM 118,-; approx. US \$ 54.90 ISBN 3-540-10672-3 Distribution rights for the German Democratic Republic: Gustav-Fischer-Verlag, Jena

The experimental data discussed in this thouroughly revised and enlarged English edition include examples of adaptive protein synthesis affected by light, substrates or hormones; programmed gene expression and cell specialization in bacteria, plants and animals; longrange and short-range cell-cell interactions: and toumorigenesis in plants and animals.

#### Y. A. VINNIKOV

#### **Evolution of Receptor Cells**

#### Cytological, Membranous and Molecular Levels

With a Foreword by S. Price Translated from the Russian by N. Bobrov

1982. 36 figures. Approx. 160 pages (Molecular Biology, Biochemistry and Biophysics, Vol. 34) Cloth DM 79, -; approx. US \$ 36.90 ISBN 3-540-11083-6

In this monograph, the author sets forth a unifying theory of sensory receptor mechanisms that is both unique and imaginative. In addition to being a valuable extension and updating of the author's previous work in this series, this book also provides an especially fine review of the Soviet literature on cytology and molecular biology.

#### Trace Element Metabolism in Man and Animals

Proceedings of the Fourth International Symposium (TEMA-4)

Editors: J. McC. HOWELL, J. GAWTHORNE, C.L. WHITE

1982. Approx. 740 pages Cloth DM 149, -; approx. US \$ 69.40 ISBN 3-540-11058-5

**Contents:** Introduction. – Antimony. – Arsenic. – Barium. – Beryllium. – Boron. – Cadmium. – Cobalt. – Copper. - Chromium. - Fluorine. - Lead. Manganese. – Mercury. – Molybdenum. – Nickel. – Selenium. – Silver. – Tin. – Vanadium. – Zinc. – Trace elements in the future. - Appendix A: Conversion factors. - Appendix B: Glossary. - Appendix C:

Indicator organisms. - Index.

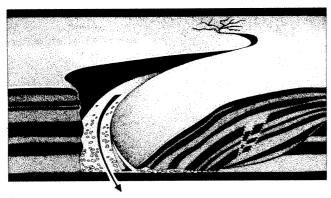

#### E. SEIBOLD, W. H. BERGER

#### The Sea Floor

#### An Introduction to Marine Geology

1982. 206 figures. Approx. 230 pages DM 46,-; approx. US \$ 21.40 ISBN 3-540-11256-1

The Sea Floor is designed to acquaint students and interested laymen with the most important results achieved in geology over the last two decades and the scientists who brought them about. Written by two of marine geology's leading exponents, it lays the groundwork for studies in geology, oceanography, and environmental sciences by summarizing modern insights into tectonics and marine morphology, the geologic processes at work on the sea floor, and the earth's climatic history as recorded in deep sea sediments.

Schematic diagram showing the generation of longitudinal crossbedding on the point bar of a tidal creek.

# Crustal Evolution of Southern Africa

#### 3.8 Billion Years of Earth History

By A. J. TANKARD, M. P. A. JACKSON, K. A. ERIKSSON, D. K. HOBDAY, D. R. HUNTER, W. E. L. MINTER

1981. Approx. 194 figures. Approx. 480 pages Cloth DM 118, –; approx. US \$ 54.90 ISBN 3-540-90608-8

Six experts have collaborated to make this book a modern, process-oriented approach, focusing on the dynamics of crustal structure.

"In the book", B. F. Windley writes in the foreword, "the reader will find a detailed review of factual data, together with a balanced account of interpretive models."

With outstanding maps and illustrations prepared especially for this volume, **The Crustal Evolution of Southern Africa** is an authoritative, multidisciplinary approach to a region of great geological importance.

#### R. SAID

# The Geological Evolution of the River Nile

With Appendix III by F. P. Bentz, J. B. Hughes

1981. 73 figures. VIII, 151 pages Cloth DM 148,-; approx. US \$ 68.90 ISBN 3-540-90484-0

This unique text presents a new explanatory hypothesis for the origins and evolution of the River Nile. Tracing the geological history of the River Nile from its origins in the late Miocene period – when in response to the lowering sea level of the desiccating Mediterranean, its excavation began – to the River Nile today, a fascinating geological history of one of the world's most famous rivers is told.

# **Geology of the Northwest African Continental Margin**

Editors: U. v. RAD, K. HINZ, M. SARNTHEIN, E. SEIBOLD

1982, 370 figures. Approx. 700 pages Cloth DM 110,-; approx. US \$ 51.20 ISBN 3-540-11257-X

Contents: Introduction. – Structure and Geodynamic Evolution of the Continental Margin. – Comparison of the Northwest African and Northeast American Margins. – Evolution of Volcanism. – Cretaceous Stratigraphy, Sedimentation and Paleoenvironment. – Cenozoic Stratigraphy, Sedimentation and Paleoenvironment. – Inorganic/Organic Geochemistry.

# Ore Genesis - The State of the Art

A Volume in Honour of Professor Paul Ramdohr on the Occasion of his 90th Birthday With Special Reference to His Main Scientific Interests Editor: G. C. AMSTUTZ

1981. Approx. 320 figures, approx. 50 tables. Approx. 800 pages Cloth DM 145,-; approx. US \$ 67.50 ISBN 3-540-11139-5

Springer-Verlag Berlin Heidelberg New York

#### **PUBLICATIONS**

# Energy considerations in electrolytic processes

This volume contains 12 of the papers delivered at a symposium sponsored jointly by the SCI Electrochemical Technology Group and the Institution of Mining and Metallurgy, and held during the first week of July 1980. Topics covered include the role of electrolysis in metal extraction today; energy comparisons in modern zinc production; potential for fused salt electrolysis in metal winning and refining; and tankhouse design and scale factors relating to energy conservation. Pp vi + 132 ISBN 090100 166 X

Price: £14 (A4, paper) Published: July 1980

#### **Desulphurisation techniques**

The report of a European Federation of Chemical Engineering working panel on aspects of chemical engineering in the environment, chaired by Professor Giuseppe Ferraiolo of Genoa University, this volume contains general information and data on present European and world sulphur emissions, and legislative aspects of the problem; extensive information about desulphurisation techniques before, during and after combustion; and a discussion on the economics of various desulphurisation techniques. Pp viii + 208 ISBN 090100 1651 Price £20 (A5, limp-bound) Published: June 1980

Hydrometallurgy '81

This volume contains 50 papers from the recent highly successful conference held in Manchester, England, and sponsored by the SCI's Solvent Extraction and Ion Exchange Group. Papers are grouped under a variety of headings—leaching, solid-liquid separation, membrane processes, ion exchange, solvent extraction, and electrolytic processes—and

make a major contribution to understanding the state of art in this technologically vital area. Pp vii + 444, ISBN 090100 1716 Price: £40 (A4, paper) Publication: July 1981

# Second European Congress of Biotechnology - Abstracts

This volume contains abstracts of the plenary session and symposia lectures, and of the poster sessions, given at ECB-2 in Eastbourne, 5-10 April 1981. It provides an invaluable overview of current activities in the fast growing field of biotechnology, with sections devoted to industrial applications of genetics, bioreactor design and performance, downstream processing, renewable energy sources, food biotechnology and many other key areas. Pp iv + 301, ISBN 090100 172 4 Price £10 (A5, limp-bound) Published April 1981

# Marine corrosion on offshore structures

This volume contains 13 papers from a major conference held in Aberdeen, Scotland, in October 1979. In some cases, papers are illustrated in full colour to provide added clarity to the material discussed. Topics covered include methods of inspecting, monitoring and sampling marine growths on offshore steel structures. prediction of corrosiveness of seabed sediments, corrosion with seawater systems on offshore platforms, and responsibility for safety and health offshore Pp vi + 115, ISBN 090100 170 8 Price £16 (A4, paper) Published April 1981

# Reclamation of contaminated land

This volume contains nearly 60 papers and discussion reports from the highly successful symposium held at Eastbourne in October 1979. Subjects covered include problems of metal contamination, hazards,

rehabilitation, environmental interests, legal issues and financial aspects. The volume also contains a transcript of the stimulating panel discussion which formed a highlight of the symposium.

Pp vii + 588 ISBN 090100 168 6 Price £40 (A4, paper)

Published November 1980

Sulphur emissions and the environment

These volumes contain papers, discussion and 'afterthoughts' from an international symposium held in London in May 1979. They provide a unique collection of expert opinion on the practical aspects of sulphur emissions. Pp xii + 522 (in 2 vols) ISBNs 090100 158 9/090100 169 4 Price £40 (A4 paper, ring-bound) Published January 1981

#### Second International Symposium on Roofs and Roofing

Volume 1 Edited by J O May This volume contains nearly 60 papers from an international conference sponsored by the SCI's Road and Building Materials Group and the Agrément Board, and held in Brighton, England, from 21 to 24 September 1981. All aspects of new technology in the roofing field are covered, with contributions from many countries, including USA, UK, India, Canada, France, Norway, Italy and the People's Republic of China.

Pp vi + 619, ISBN 090100 174 0 Price: £40 (A4, paper) Publication: September 1981

Copies of all these publications may be obtained directly from the Publications Dept, Society of Chemical Industry, 14/15 Belgrave Square, London SW1X 8PS, England. Prices include postage and packing at surface mail rates. For airmail delivery there is a surcharge based on the weight of the volume.

Members of the SCI are entitled to a 50 per cent discount on the published prices, provided that a remittance is sent with their order.

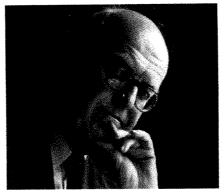

SOCIETY OF CHEMICAL INDUSTRY, 14 BELGRAVE SQUARE, LONDON SW1X 8PS, ENGLAND

who introduced group theory into physics (p.145): that had been done by Wigner in the late 1920s. Group theory then became one of the customary tools of theoretical physicists. Gell-Mann applied it ingeniously and successfully to the problems of particle physics.

In two cases Snow's tendency to sum up people in a few sentences leads to injustice. On p.112 he states bluntly that "General Groves was a singularly bad choice for his job". I have no well-founded personal opinion, but I notice that A.H. Compton writes in his Atomic Quest — by a curious coincidence also on p.112 — "The nation was fortunate indeed in the selection of General Groves for this task". Also, it cannot be denied that Groves's short-term mission was efficiently accomplished. The second case is worse. On p.26 Snow writes

... Lenard who, incidentally, as an old man was one of the only two eminent German scientists who became active spokesmen for the Nazi faith. (The other was Werner Heisenberg, a great theoretician...).

Such parenthetic calumny should not go uncorrected. Certainly, Heisenberg was a German patriot. He loved his country; the German language and German culture meant much to him (but in the early 1920s the *Jugendbewegung* to which he belonged was not a nationalistic group). We may regret that he let his love for his country prevail over his objections to the Nazis, we may wish that he had taken a firmer and more courageous stand against them. And I admit that on the one occasion I met him during the war he showed little

C.P. Snow 1905-1981

understanding for the feelings of people in an occupied country. But he always maintained his integrity as a physicist and at one time he was even under severe attack by members of the Lenard group, because he continued to express his belief in quantum theory and relativity. It is utterly wrong to mention him in one breath with Lenard.

Nevertheless, despite these detailed criticisms, I consider *The Physicists* a valuable book. Its theme is important, its basic structure sound and it contains many incisive remarks and interesting side-lights. I read it with pleasure and profit, and am convinced that many will do likewise.

H.B.G. Casimir studied theoretical physics at Leiden, Copenhagen and Zürich, worked in low temperature physics at Leiden and later joined the Philips Company at Eindhoven. He is a foreign member of the Royal Society and a former President of the European Physical Society.

# Philosophy in an uncertain world

John Polkinghorne

Divine and Contingent Order. By Thomas F. Torrance. Pp.162. ISBN 0-19-826658-8. (Oxford University Press: 1981.) £9.50, \$27.59

PROFESSOR Tom Torrance is a distinguished theologian, the chief apostle in this country of Karl Barth, whom many would regard as the most significant figure in twentieth-century theology. In addition, Torrance is one of the few British theologians to have taken a serious interest in what science has to say about the world. This reflects itself in Torrance's strongly objectivist approach to theology, and it is no accident that one of his best known books is called *Theological Science*.

His latest work is concerned with the assessment of the significance of the contingency that we find in nature. We can distinguish at least four senses in which such contingency is present: (i) The laws of nature are not necessary, in the sense that their form cannot be determined by pure thought alone but has to be obtained from experimental observation. The recognition and exploitation of this is what gave

modern science its superiority over that of the ancient world. (ii) The parameters appearing in those laws, such as the fine structure constant, take values which can only be determined empirically. Sir Arthur Eddington tried to deny this in Fundamental Theory and came to grief. However an interesting gloss on the values of these constants is provided by the anthropic principle which recognizes limitations to be satisfied in a universe in which we can emerge as observers. Torrance only mentions this in a footnote; it deserved greater consideration on his part. (iii) In the great diversity of things that happen there are unforeseeable concatenations of circumstance. This is the "chance" that Monod saw operating in the emergence of life and which for him (but not for me) caused the fabric of significance to crumble. (iv) There is the radical unpredictability of quantum mechanical observation and (I would say) the action of the will, both topics which we do not understand very well.

It seems important to discriminate between these four aspects of contingence,

Circle No. 25 on Reader Enquiry Card.

but I did not feel that Torrance always adequately observed the distinction.

As a matter of historical fact the Christian doctrine of creation helped men to recognize (i) and (ii) and so made possible the scientific revolution. By a curious twist, the Newtonian mechanical world view then tended to abolish the recognition of (iii) and (iv).

The presence of contingence in the world is combined with a high degree of intelligibility which enables us to understand it. Torrance says "The intelligibility of the universe provides science with its confidence but the contingence of the universe provides science with its challenge" (p.58). Such a view of the world is certainly consistent with the doctrine that it is the work of the sovereign will of the Creator and that its rationality is the reflection of his mind. Torrance seems to argue that only such a doctrine is possible but I cannot agree that there is that degree of intellectual compulsion. He sees creation as implying two complementary aspects. First, the world is wholly dependent on God since without his sustaining it would collapse back into nothingness. From this comes its contingent order. Second, the world is other than God (no pantheism!) so that he has made it to stand apart from him. The first aspect is the concern of theology; the second that of science whose method is to proceed etsi deus non daretur, as if God did not exist. A true understanding requires a synthesis of these aspects.

A test of any world view is its understanding of evil. Torrance equates evil with disorder but nevertheless (rightly I believe) does not go along with Augustine and Aguinas in seeing it as just the absence of good. I thought his discussion needed a more thorough-going eschatological dimension. Also, I did not always recognize the world of science as Torrance described it. He attributes a release from the shackles of Newtonian necessity to the creation of the field concept and to the genius of Einstein. I cannot see that. Partial differential equations have propagation properties as rigorous as those of ordinary differential equations and causality finds its place within the lightcone of relativistic physics. Further, I did not understand his attitude to mathematics. He does not like to accord it true intellectual independence (that would be dangerously Platonic and Plato's ideas are possible rivals to God in his eyes) so he says it has a "natural bond with nature". Again, I do not see that.

The book is written in a style which might be described as "Scottish professorial", a sort of intellectual cousin to the elaborate castellation of Scottish baronial. Certainly, it does not make for easy reading or rapid assimilation.

John Polkinghorne, formerly Professor of Mathematical Physics at Cambridge, is a Fellow of Trinity College and an Anglican clergyman.

# How not to make a splash in science

Robert Ubell

Polywater. By Felix Franks. Pp.208. ISBN 0-262-06073-6. (MIT Press: 1981.) \$15, £9.30.

In the early 1960s in an obscure laboratory in Kostroma, 190 miles from Moscow on the upper Volga, an equally obscure research scientist, Nikolai Fedyakin, stumbled on a surprising phenomenon. Looking at how liquids behave in very narrow capillaries, he watched as a dense new liquid formed in neighbouring empty tubes.

In Moscow, the renowned physical chemist B.V. Deryagin quickly recognized the possible implications of Fedyakin's 'discovery' and took it for his own. He set an entire laboratory to work on it, published results widely and campaigned for the recognition of anomalous water at Faraday Society and Gordon Research conferences. The new liquid was 15 times denser than normal water, boiled at temperatures much higher than 100°C and froze, without forming ordinary ice, at under -30°C. For a time, Western scientists either yawned or sneered. Some guessed it wasn't water at all, but the result of contamination. Yet excitement grew, and in England attempts were made to replicate the Russian work. J.D. Bernal, in private, called Deryagin's achievement "the most important physical-chemical discovery of this century".

The US Office of Naval Research jumped in next, sensing that the mysterious new form of water might have military uses. Ripples of interest swelled to waves: the liquid was given a name — polywater — and busy scientists suddenly found the time and money to work on what they had seen as a mere curiosity the previous week. Respected researchers and the overzealous alike scrambled to make their mark, even though, at most, only a few drops of polywater had ever been collected.

In 1973 the bubble burst. In a brief, dignified note in *Nature*, Deryagin reported that he and his colleagues had finally found it impossible to grow polywater from ordinary water. The unique qualities claimed earlier "should be attributed to impurities rather than to the existence of polymeric water molecules". The emperor was not well dressed.

Felix Franks escaped the perils of the polywater controversy, but as a distinguished surface chemist and an authority on water he was close enough to record it all. The result is this book. To his great credit, Franks treats those who believed and those who didn't with an even hand, praising little, blaming less. This is a skilfully made book, wise, urbane,

#### Nature of "Anomalous Water"

Many experiments have corroborated the phenomenon involving the formation of condensates with anomalous properties from the vapours of water and other liquids on silicate surfaces. But the nature of this phenomenon remained obscure for a long time and widely differing hypotheses were put forward to clarify it, one of them involving the formation of stable associates of water molecules (H<sub>2</sub>O)<sub>n</sub>. This hypothesis was first formulated by us<sup>1-4</sup> and was developed further by Lippincott *et al.*<sup>5,6</sup>.

We have established that there are no condensates both free of impurity atoms and simultaneously exhibiting anomalous properties. Consequently, these properties should be attributed to impurities rather than to the existence of polymeric water molecules.

Consequently, the anomalous properties of condensates may be explained, not by the formation of a new modification o water, as was previously supposed, but by the peculiar features of a reaction taking place between the vapour and solid surfaces in the process of condensation. Many aspects of the mechanism of formation of anomalous condensates have not yet been fully clarified. This especially applies to the formation of anomalous condensate on MgO surfaces<sup>19,20</sup>. Only the general features of the phenomenon are clear as yet; thorough investigation by those studying processes involving the interaction of vapours and solid surfaces is clearly required.

The Institute of Physical Chemistry, USSR Academy of Sciences

B. V. DERJAGUIN N. V. CHURAEV

The end of polywater. Extracts from the paper by Deryagin (Derjaguin) and Churaev, published in *Nature* on August 17, 1973.

#### **COPING WITH THE BIOMEDICAL** LITERATURE: A Primer for the Scientist and the Clinician

Ed: K. S. Warren (The Rockefeller Foundation)

Twelve of the most influential scientific editors and library directors in the US delineate proven methods for utilizing the major forms of information available. Contains sections on the structure of scientific literatures, including quality-based concepts; how to use a library, including indexing systems and literature searching; the purpose of medical journals; and how to design an experiment and interpret the results statistically. 233pp September 1981

# NEW BOOKS FROM ALLEN & UNWIN

#### **British Rivers**

Edited by John Lewin (UCW, Aberystwyth)

The physical nature of British rivers is described and interpreted here by seven leading scientists. Despite intensive research in recent years in universities, research institutes and water authorities, no such summary has appeared before. The book will be highly relevant to students and scientists in a wide range of disciplines as well as to those professionally engaged in environmental management and the water industry.

#### Contents

River systems and river regimes - R.C. Ward (U. of Hull): Contemporary erosion and sedimentation - J. Lewin (UCW, Aberystwyth); Mountain streams - M.D. Newson (Institute of Hydrology); Channel form and channel changes ### R.I. Ferguson (U. of Stirling); Water quality – D.E. Walling & Bruce Webb (U. of Exeter); River management – T.R. Wood (Severn Trent Water Authority)

Available 232 pp 92 line and 21 tone illustrations 246 x 189mm 0 04 551047 4 Hardback £20.00/\$50.00

#### Coal in Britain: An Uncertain Future

Gerald Manners (University College, London)

With increased direct subsidies by the Government to the National Coal Board, Gerald Manners' critical analysis of the Board's declared development and investment strategy is particularly timely. Examining in detail the best evidence in the likely demand for British coal over the next 20 years Professor Manners shows that it is hard to justify the production of high cost coal from old mines and the output of proposed new ones with the challenge of low-cost imports as well as strong opposition by environmentalists to proposals to mine areas of outstanding natural beauty such as the Vale of Belvoir. He therefore urges changes in both the scale and timing of the modernisation and investment programme. This book will be of interest to all who are concerned about the management of a valuable national resource.

## Soil Survey and Land Evaluation

David Dent and Anthony Young (U. of East Anglia)

The related techniques of soil survey and land evaluation play an essential part in the planning and management of land resources. This book provides a concise and practical introduction to these techniques and procedures, for professional surveyors, students and potential users of surveys. The wide range of applications of surveys is emphasised throughout and there is much practical advice on planning a soil survey, taking into consideration the different scales of accuracy, timing and cost. The concepts of land evaluation are also discussed giving a review of both established and new methods for land capability classification and land suitability evaluation. The authors' wide-ranging experience both in developed countries and the Third World contributes to the authority of this practical treatment.

National Parks: Conservation or Cosmetics?

Ann and Malcolm MacEwen (University College, London) This provocative book shows that government policies for agriculture and forestry are actually working against the best interests of conservation management and that the whole national park system is in need of extensive overhaul. Using their unique combination of knowledge and work in the fields of planning, architecture and landscape design, the authors present a radical challenge to conventional attitudes and entrenched interests. They highlight the need for the principles of conservation to pervade all agricultural and rural planning policies, if such policies are to be any more than cosmetic in their effects. This book will be essential reading for all concerned with the management of the countryside.

#### Soils and Landforms

An Integration of Geomorphology and Pedology John Gerrard (U. of Birmingham)

This book provides a vital integration of geomorphology and pedology, two major divisions of the Earth Sciences which hitherto have been treated separately. The value of soils as stratigraphic indicators and as guides to an understanding of landform evolution is being increasingly recognised; this book provides much of the background to these themes. The applied aspects of geomorphology and pedology are stressed throughout with examples taken from land management studies. It should therefore be of interest to geographers, soil scientists, geologists and those concerned with studies in environmental science.

#### Time Resources, Society and Ecology Vol. I Pre-industrial Societies

Tommy Carlstein (U. of Lund, Sweden)

Like energy, land and water, time is a limited resource. This study represents an attempt to place time resources in an holistic perspective and to examine the time dimension in terms of ecology, technology, social organisation and spatial structure of the human habitat. Geographers, social anthropologists and human ecologists should find this work directly relevant to their interests in understanding the interactions between man and environment.

Environmental Archaeology Myra Shackley (U. of Leicester)

This book presents a comprehensive survey of environmental methods in archaeology, which have proliferated over the past twenty years. The approach is systematic, designed to enable the reader to learn about the wide range of available techniques, with separate chapters on sediments and soils, micro organisms, ferns and mosses, pollen analysis, wood and charcoal, seeds, fruit and nuts, molluscs, insects, parasites, animal bones, fish remains and birds. It should serve both as a text for undergraduate students and as an introductory guide for the serious amateur.

amusing. For outsiders, Franks pencils in a deft, accessible guide to what is known about water, reveals how scientists communicate with each other and offers some serious and not-so-serious asides. Especially rich are the press reports — Franks finds fault with popular magazines and newspapers for inflaming an already hot scientific debate.

Recognizing that it is easier to reconstruct history than to learn from it, Franks, nonetheless, attempts the exercise. One lesson is that since competition is the driving wedge behind science, the race for

priority created the polywater episode; other bungles like it are inevitable, given enough money and freedom. But competition may not be essential. Other ways of getting results may be just as good, if not better. We know that there is an opposing tendency for investigators to collaborate, rather than beat each other to the punch. Competition, like polywater, may be merely an artefact of our times.

Robert Ubell is the American Publisher of Nature. During the "polywater years" he was Editor-in-Chief at Plenum, where both Felix Franks and B.V. Deryagin were his authors.

Herman Mark

The Chain Straighteners. Fruitful Innovation: The Discovery of Linear and Stereoregular Synthetic Polymers. By Frank M. McMillan. Pp.207. ISBN 0-333-25929-7. (Macmillan Press, London: 1981.) £17.

THE steady and slowly moving mainstream of science and technology is occasionally interrupted and enlivened by unexpected events which accelerate it and eventually change its direction into new and hitherto inaccessible domains. Popularly known as "breakthroughs", such drastic evolutions have, since the last war, occurred in mathematics through the advent of electronic computers, in physics as a result of nucleonics and laser optics and, probably best known, in the life sciences through the discovery of helices in the structure of proteins and of double helices in that of nucleic acids. This book relates in a captivating and intriguing manner the story of another breakthrough which occurred in the mid-1950s in organic chemistry and the closely related field of polymer science and technology

It started in the late 1940s when Dr Karl Ziegler, then Professor of Organic Chemistry at the University of Halle on the Saale, became Director of the Max Planck Institute for Coal Research in West Germany. Ziegler, already a well known and distinguished scientist at that time, had worked for years on a family of substances at the border of inorganic and organic chemistry known as metallorganic compounds and had specifically concentrated his efforts on the alkyl derivatives of aluminium. One particularly representative member of this family, triethylaluminium, is a colourless, volatile liquid, highly flammable and even explosive, requiring extreme skill in its preparation and handling. But these problems, a consequence of its high reactivity, attracted Ziegler rather than deterred him; and his experimental virtuosity allowed him to dominate this field for a number of years. In the early 1950s he observed that ethylene could be added to triethylaluminium in such a manner that hydrocarbon chains from 10 to 20 carbon atoms were obtained. Ethylene was, at that time, a readily available and inexpensive raw material of the petroleum industry and the resulting aliphatic chain compounds were valuable starting materials for detergents, emulsifiers and plasticizers. No wonder that several chemical companies — for instance, the Montecatini Company in Italy — started to negotiate with Ziegler about a joint evaluation of his invention. Evidently his new process was interesting and useful.

But the real sensation came a year later. As a result of a strange sequence of trial and error steps, Ziegler and his associates found that through the addition to the aluminiumalkyl of heavy metal salts ethylene could be rapidly transformed into linear, high molecular weight polyethylene. Even though there already existed a well established commercial process the ICI process — for the production of a non-linear and somewhat softer type of polyethylene, and even though a linear polyethylene - Marlex of the Philips Petroleum Company — was on the verge of becoming commercial, the Ziegler discovery acted like a bombshell. The complete novelty of the catalytic system, the mild conditions of the polymerization and the resulting simplicity of the equipment produced a rarely experienced rush of licences for the new process. Careful laboratory work with difficult materials, intuitive appraisal of unexpected results and energetic pursuit of all available avenues had created a new tool for the polymer chemist — the Ziegler catalysts and started a new and important branch of polymer technology.

But, to the delight and surprise of the reader, this is only part of the story of the book. Dr Giulio Natta, directing the Chemistry Department of the Polytechnic Institute of Milan, happened to be a consultant for the Montecatini Company and, in due course, became familiar with the existence of Ziegler catalysts. He applied

The Nobel Prize winners — Ziegler (left) and Natta listen as Professor Fredga makes the presentation speech, Stockholm, 1963.

them on propylene instead of on ethylene and, of course, obtained polypropylene. Considering that, at that time, no high polymers of propylene were known, this was an important contribution to polymer technology. It was dwarfed, however, by Natta's discovery that the use of Ziegler catalysts

permitted the preparation of several species of polypropylene and other vinylpolymers differing from each other only by the steric arrangement of the substituents. Until that time stereospecific catalytic power had only been observed with natural enzymes: it is understandable, therefore, that the discovery of the existence of dozens of stereo-regulated polymers and their precise identification added to this commercial

success a major scientific sensation.

Dr Frank McMillan, as a contemporary of all these events, was manager of a large industrial research laboratory and has, therefore, acquired a special feeling for the intricate relationship between fundamental research and practical application.

Needless to say, the alluring commercial features of the new catalysts and their novel applications attracted, with increasing intensity, the interest of many large companies. As a result of their permanent and strong participation, there came the day when the predominant question was formulated: "What belongs to whom?" a question which has been debated for the last 25 years. Understandably, the litigations have led to several confrontations, and in this domain the author is a true master of ceremonies, distributing fame and blame with restraint and distinction. All this makes excellent reading: entertaining, instructive and sometimes even philosophical. In several instances he offers specific warnings to avoid certain mistakes in research and development and even in the recording of results. The clarity of his exposition should certainly convince readers to avoid such mistakes in future. But, very probably, in doing so, they will make others.

Herman Mark is Dean Emeritus of the Polytechnic Institute of New York. At the time of the discoveries described in the book, he was in contact with two institutes in Germany and Italy and contributed some ideas to the mechanism of Ziegler-Natta polymerization.

OLD SCIENCE & MEDICINE

# Jean Baptiste Rousseau revisited

Gunther S. Stent

The Double-Edged Helix: Science in the Real World. By Liebe F. Cavalieri. Pp. 196. ISBN 0-231-05306-1. (Columbia University Press: 1981.) \$14.95, £10.80.

THE latter-day metamorphosis of molecular biology from the esoteric speciality of a small band of aficionados into an academic juggernaut and billion-dollar industry, and its technical and moral implications, have not been slow to draw the attention of sociologists and ethicists of contemporary science. Indeed, the writing of books about the banishment of molecular biology from the Garden of Eden has become a minor cottage industry. The Double-Edged Helix by Liebe F. Cavalieri, a biochemist working at the New York Sloan-Kettering Institute for Cancer Research, is another contribution to this literature. Subtitled Science in the Real World, Cavalieri's book addresses the politics of the recent controversy surrounding the development of recombinant DNA technology. One of his chapters is entitled "Rousseau Revisited", and since Cavalieri makes no allusion to Jean Jacques, the philosopher, he appears to be revisiting Jean Baptiste, the poet, who was prosecuted and exiled from France in 1712 for libelling his colleagues.

As presented by Cavalieri, the situation is as follows. There are some people who believe that genetic engineering by recombinant DNA methods is dangerous and should be closely controlled. They are "thoughtful", "unusually frank" and "valiant"; they "have a conscience", "question neatly" and "testify" before government bodies "in the public interest". Other people, by contrast, believe that there is little or no danger in this enterprise and oppose strict controls on recombinant DNA research. They are "simplistic", "self-serving" and make "crusades"; they have "myopic vision" and form part of the "power structure", "smack of scientific elitism" and "lobby" before government bodies, "snowing" them with "massive campaigns" to satisfy spurious" and "inane" needs.

Moreover, many of these opponents of strict controls happen to be holders of the Nobel Prize, "an exceedingly dangerous device" that gives each of them "virtual limitless power . . . within his institution and among his colleagues": others are merely members of the National Academy of Sciences, that "tends to favor special interests", "does not represent the bulk of the national science effort" and has a president, or "high priest", who "muddies the water" and "breaches . . . canons of scientific propriety". I think there is little chance that many readers of Nature will find merit in this book. But it may be useful all the same to dissect and review briefly Cavalieri's main propositions.

1. Molecular-genetic engineering is morally wrong because "the natural gene pool of the earth [is] an inalienable birthright". Moreover, we must not cross the "natural genetic barrier between species which protects the integrity of the species" as is generally done in recombinant DNA experiments. This is not a political argument, as Cavalieri thinks it is, but a theological, non-utilitarian one that has meaning only within the Judeo-Christian tradition. Since God has obviously permitted the natural gene pool of the Earth to change over evolutionary time and allowed man to change it since Neolithic times, this proposition, if true, would present us with another paradox of theodicy. In any case, what it is we are and are not allowed to do genetically hinges on the hermeneutics of Genesis 1:26 versus Genesis 2:7 and the sense in which God gave man dominion over the animals. Hence the discussion must focus on whether or not our divine grant of "dominion" includes permission to alter the natural gene pool and cross species barriers. Genesis 9:1 is relevant here, in that the passengers of Noah's Ark provide the exegetically pertinent explication of "species". And as regards species crossing, Cavalieri's proposition is supported by Leviticus 19:19: "Thou shalt not let thy cattle gender with diverse kind; thou shalt not sow thy field with mingled seed". I believe it is possible to produce a rational argument according to which a devout Jew, Christian or Muslim should not undertake recombinant DNA experiments. In a secular context, however, the gene pool and species-crossing proposition is irrational.

2. Molecular-genetic engineering is potentially very dangerous, and hence should not be carried out, or, at least, should be closely controlled. This utilitarian argument is the centrepiece of the *The Double-Edged Helix* and, although it can be simply stated, it is actually quite complex. First, as far as the dangers themselves are concerned, they can be subdivided into short term — "immediate biohazards that could result from a laboratory accident" — and the long term — "irreversibility of the organisms themselves and the irreversible socioeconomic entrenchment that will result from the

successful use of recombinant organisms, regardless of their side effects". As for the immediate biohazards, there seems to be no disagreement regarding the possibility that such hazards may exist. What is under dispute is who, if anyone, is competent to assess these hazards and decide whether there is or is not a reasonable chance of averting them.

According to Cavalieri, the molecular biologists who are actually engaged in genetic engineering cannot be trusted to make this assessment, because their selfinterest causes them - Nobel Laureates, Academy members and just plain bench workers - to make dishonest risk appraisals and use their "clout" to sink even the timid guidelines by means of which prudent government administrators and legislative bodies sought to protect the common weal. So it is left to investigative reporters, consumer and environmental protection organizations, and "socialresponsibility-in-science" groups, whom Cavalieri cites mainly in support of his arguments, to identify the substantial biohazards associated with recombinant DNA. Of just what these hazards actually consist is, however, not - probably for lack of expertise - clearly or credibly spelled out. If Cavalieri's low opinion of the moral fibre of what he calls the "science community" were an accurate perception, the real world, being deprived of reliable expert opinion on vital scientific matters, would really be in serious trouble.

Fortunately I can recognize the scenario that has the legion of molecular biologists currently engaged in research using recombinant DNA techniques, carelessly risking the survival of mankind to satisfy their idle curiosity or venal cupidity, as merely a paranoid fantasy.

As for the long-term hazards, Cavalieri finds that in them lie "the most serious dangers of recombinant DNA technology". But, of just what these serious dangers consist Cavalieri spells out even less clearly than he does for the shortterm biohazards. He merely points to the history of twentieth-century technology, which shows that many developments originally thought to be benign later turned out to have unanticipated malign sideeffects. Thus Cavalieri calls on the journalist John Lear to remind us that Henry Ford's invention of the massproduced automobile, though it provided mobility to Everyman, turned out to deprive him of a livable habitat. And Cavalieri wants us to "remember the nuclear spills, and how we were reassured about the safety of nuclear power plants". So how does "the irreversible socioeconomic entrenchment of recombinant organisms" present a long-term danger? Because it will

provide technological fixes for past failures that cannot be rooted out at the source. Thus we try to find a technique for curing lung cancer while we continue to . . . advertise cigarettes, and we develop oil-eating bacteria to clean up oil spills,

instead of redesigning oil tankers or reexamining our energy-intensive and wasteful economy or making a serious effort to shift to renewable and ubiquitous energy sources.

That in the socialist countries, where there is no advertising, cigarette consumption is even higher than in the capitalist world, and that work is already in progress to produce genetically engineered microbes intended to provide a renewable energy source which would do away with oil tankers altogether, is apparently not known to Cavalieri. But for him the most ominous long-term hazard is the application of recombinant DNA techniques to the human genome. He admits that there is the possibility of performing "gene therapy" on a number of hereditary defects. But Cavalieri finds that it is not "a high priority line of research to be chosen in preference to other directions" and its benefits pale in camparison with the spectre of eugenics, which 'received considerable support from industrialists like the Harrimans, Kelloggs and Carnegies". Though "its demise was aided by the repugnancy of emerging Nazism . . . with the development of new genetic techniques the eugenics movement in America could rise again".

To this it can be said, first, that whereas it is true that the project of improving the human "gene pool" by eugenic methods has fascinated many prominent geneticists, it is also a fact that despite the long-time availability of techniques (such as artificial insemination) for implementing eugenic goals by methods more humane than those practised in Nazi Germany, wide-scale eugenics has not come into use in any democratic society. So, there seems to be a firm (probably religiously rooted) resistance to eugenics, leaving its advocacy mainly to scientistic cranks. Second, and more importantly, it may be the case that any answer to "the classical question: who decides what is a defect?" could lead to procedures "clearly open to abuse". But, all the same, opposing on those grounds the use of diagnostic, prophylactic and corrective procedures in medical genetics reveals a lack of genuine empathy with and concern for people in the real world, since there are hereditary disorders that every person would judge to be defects with which no human being ought to be born. Thus Cavalieri's argument against genetic engineering from long-term hazards consists merely of general cant about Henry Ford, nuclear spills and the Nazis, and puts forward no specific prognosis that can be critically examined and discussed. Rather, just as does the argument from immediate biohazards, this argument, too, merely indicates a radical lack of faith in the honesty and wisdom of the leaders responsible for the management of our democratic society and of our scientific colleagues.

3. The potential benefits of moleculargenetic engineering are too small to offset the enormous risks. "The now familiar list of potential benefits that may accrue from

recombinant DNA includes . . . the production of insulin . . . antibiotics . . . vitamins and hormones . . . and . . . food crops. . . . Do we need them?". Cavalieri answers "no". As for insulin, a "thoughtful approach to the problem of diabetes ... was given by Harvard's Professor Ruth Hubbard" who declared insulin to be a "technological gimmick". She counsels that we should rather try to find "the causes of diabetes, which are, as with all other diseases, heavily influenced by social and environmental factors". And as for antibiotics, vitamins and hormones, in the United States we have already 20,000 pharmaceutical products in medical use, when "the World Health Organization has indicated that only 210 drugs would be sufficient to fill world health needs". And as for food crops, "we must not let our understandable sympathy for the hungry people of the world lead us into mistaking the cause of the problem, which is not one of production or quality but of distribution and utilization. The world now produces enough grain to feed everyone adequately". That is to say, abundant food is available to feed the hungry, if only the nations with undernourished populations would organize better politically and economically so that they can buy food from the affluent countries that waste their food surpluses anyhow. So "no real need has yet been brought forward to justify the serious ecological hazards of introducing major disturbances into the complex balance of things" by recombinant DNA methodology.

It is not necessary here to enter into a dis-

cussion of the merits of Cavalieri's claims. For even if these claims were just, the finitude of his list of potential benefits and his additional pronouncement that "we are no longer in an area when practical applications of scientific research are unforeseeable and the human consequences unknown" show a demagogic refusal to allow that what is sauce for the goose is also sauce for the gander. If it is the case that, as Cavalieri claims elsewhere, history teaches us that the long-term hazards of scientific and technological developments are always unforeseeable, he cannot in good faith allege that the time has come when all their benefits are foreseeable. Moreover, Cavalieri's competence to discuss, not ethics, but modern DNA research is put into question by his failure to mention the amazing advances that recombinant DNA techniques have brought to our understanding of the molecular organization of genetic structures in the past three or four years. An author of a book on recombinant DNA that appeared in 1981 who does not mention the discoveries of the fragmentation of eukaryotic genes and the mechanism of generating the diversity of antibody specificity, neither of which could have been made without the use of recombinant DNA methods, commands just about as little credence among biologists as one who, in the 1960s, would have failed to mention the discovery of the genetic code.

Gunther S. Stent is Chairman of the Department of Molecular Biology and Director of the Virus Laboratory at the University of California, Berkeley.

# A haunted house of cards

D.R. Newth

A New Science of Life: The Hypothesis of Formative Causation. By Rupert Sheldrake. Pp.229. ISBN 0-85634-115-0. (Blond & Briggs: 1981.) £12.50. To be published in the US in January 1982 by Tarcher, Los Angeles.

THE title of this book is misleadingly modest. The author is not content to propose only a new science of life, for he reassesses many features of the real world that have been revealed by natural science, and proposes that there exists a great conservative principle making itself felt as much, or more, by sub-atomic particles as in developing embryos or in the behaviour of human beings. The principle is that what happens, or has happened, can exert an influence that is without decrement in space or time upon future events of a similar kind. This influence acts to promote a repetition of what has gone before. The degree of similarity qualifying a living organism to respond to these persuasive messages appears to be conspecificity. Not all decisions or events, however, are susceptible to the principle of "formative causation".

The immediate recipient of the messages is a "morphogenetic field" which guides formal change in its associated "morphogenetic germ" until its prescriptions have been met and the "morphic unit" is finally co-extensive with the field. The morphogenetic field blends the experience of all previous similar morphic units by a process of "morphic resonance". Neither morphic resonance nor the obedience of the morphogenetic germ to the dictates of its morphogenetic field involve exchanges of matter or energy.

This, I understand it, is the burden of Dr Sheldrake's argument.

It is, of course, brave to expound in little more than 200 pages so revolutionary a denial of everything that empirical science has made seem probable. Nor should we deny some leniency to the holders of really way-out ideas. They lack the support of an established terminology, and the com-

# Announcing a new Companion Journal for Journal of Materials Science

# JOURNAL OF MATERIALS SCIENCE LETTERS

# Commencing publication January 1982

The continued popularity of *Journal of Materials Science* has recently led to a substantial increase in the number of high quality papers submitted for publication. In order to cope with this expansion without any sacrifice of quality or speed of production, it has been decided to separate the Letters section of *Journal of Materials Science* from the section devoted to Reviews and full-length papers, and to publish these short communications in a new monthly fast-publication journal, *Journal of Materials Science Letters*.

The new Journal of Materials Science Letters will have the following features:

- Rapid publication of short communications on all aspects of materials science research
- Monthly publication and distribution with Journal of Materials Science
- The present editorial team, headed by Professor W Bonfield will be responsible for both journals. Papers for submission to both journals should be sent directly to: Professor W Bonfield, Department of Materials Science, Queen Mary College, Mile End Road, London Et 4NS.
- Issues will have 40 pages and will be typeset and printed in a similar style and with the same quality as *Journal of Materials Science*, with a cover photograph chosen from the contributions
- All subscribers to *Journal of Materials Science* during 1982 will receive *Journal of Materials Science Letters* as part of their subscription

# MAMMARY TUMORS IN THE MOUSE

edited by **J. HILGERS** and **M. SLUYSER**.

A comprehensive overview of research on mammary tumors in the mouse, with historical information and a consideration of genetic,

molecular and immunological influences.

1981 xvi + 692 pages. US \$170.00/Dfl. 399.00. ISBN 0-444-80325-7.

#### PROGRESS IN ENVIRONMENTAL MUTAGENESIS AND CARCINOGENESIS

Proceedings of the 10th Annual Meeting of the European Environmental Mutagen Society, Athens, September, 1980.

edited by A. KAPPAS.

# Progress in Mutation Research, Volume 2.

This book highlights the mutagenic potential of certain food constituents and pesticides, provides a mutagenic and carcinogenic evaluation of environmental pollutants, and examines several methodological problems including a critical evaluation of the Ames test.

1981 300 pages. US \$76.50/Dfl. 180.00. ISBN 0-444-80334-3.

#### MEMBRANE TRANSPORT

edited by S. L. BONTING and J. J. H. H. M. DE PONT.

# New Comprehensive Biochemistry, Volume 2.

This volume deals with the topic of membrane transport. The book presents an up-to-date picture of the present state of knowledge in this field and several chapters contain new ideas and reviews not previously published.

1981 376 pages. US \$59.50/Dfl. 140.00. ISBN 0-444-80307-6.

#### MEMBRANE STRUCTURE

edited by J. B. FINEAN and R. H. MICHELL.

# New Comprehensive Biochemistry, Volume 1.

This volume covers all aspects of membrane structure of current interest.

The aims of this book are to identify general features of membrane structure, to discuss in considerable detail some selected aspects that have been studied intensively in recent years and to relate some of this molecular information to individual membrane functions.

1981 283 pages. US \$59.50/Dfl. 140.00. ISBN 0-444-80304-1.

# THE BIOLOGY OF THE INTERFERON SYSTEM

Proceedings of the International Meeting on the Biology of the Interferon System, April 1981.

#### edited by E. DE MAEYER, G. GALASSO and H. SCHELLEKENS.

This work is a comprehensive and up-to-date collation of information reflecting the most recent advances and developments in the interferon field and includes all topics of current interferon research. Written by leading experts, this book deals with all aspects from molecular structure to applications in humans.

1981 xvi + 472 pages. US \$63.75/Dfl. 150.00. ISBN 0-444-80360-2.

# TISSUE REPAIR AND REGENERATION

edited by L. E. GLYNN.

Handbook of Inflammation, Volume 3.

This work is concerned exclusively with the processes of repair by which

loss of tissue from whatever cause is made good. The book gives a very full and detailed description of all aspects of the repair process from the clearance of the site to the maturation of the scar. Special attention is focussed on those factors influencing the balance between regeneration and repair and between atrophy and hypertrophy.

1981 xiv + 596 pages. US \$119.25/Dfl. 280.00. ISBN 0-444-80278-9.

# DYNAMIC EXPERIMENTS IN THE ELECTRON MICROSCOPE

edited by E. P. BUTLER and K. F. HALE.

# Practical Methods in Electron Microscopy, Volume 9.

This volume, the first written on this subject deals with the possibility of using the objective region of a transmission electron microscope as a microlaboratory rather than simply the object plane of the instrument. The book surveys the principles and practice of *in situ* experimentation in both conventional microscopes and those operating at a higher accelerating potential.

1981 xvi + 460 pages. US \$83.00/Dfl. 195.00 (hardback). ISBN 0-444-80285-1. US \$39.25/DFl. 92.00 (paperback). ISBN 0-444-80286-X.

#### SUPPRESSOR CELLS IN HUMAN CANCER

edited by **B. SERROU** and **C. ROSENFELD**.

Human Cancer Immunology, Volume 2.

This volume is devoted to suppressor cells in the cancer patient. Presenting a collection of the latest concepts on the functional characterization of

subpopulations and the evidence for their presence during the evolution of tumors, the data should serve as an approach to uncovering mechanisms of action of suppressor activity and marks the beginning of a new chapter in oncology.

1981 xiv + 216 pages US \$69,75/Dfl. 164.00. ISBN 0-444-80306-8.

#### MONOCLONAL ANTIBODIES AND T-CELL HYBRIDOMAS PERSPECTIVES AND TECHNICAL NOTES

edited by G. J. HÄMMERLING, U. HÄMMERLING and J. F. KEARNEY.

# Research Monographs in Immunology, Volume 3.

This volume includes reviews from a large number of immunologists with a breadth of experience in the production of monoclonal antibodies to a wide range of antigens. These include antigens of the major histocompatibility complex of man and rodents, as well as other tissue antigens.

This volume will provide a useful introduction to the spectrum of uses to which this new technology can be applied.

1981 xvi + 604 pages. US \$99.50/Dfl. 234.00. ISBN 0-444-80351-3.

# ELSEVIER BIOMEDICAL PRESS

P.O. Box 211, Amsterdam, The Netherlands

Distributor in the U.S.Á. and Canada: ELSEVIER NORTH-HOLLAND, INC., 52 Vanderbilt Ave., New York, NY 10017

The Dutch guilder price is definitive. US \$ prices are subject to exchange rate fluctuations.

#### The Camera Obscura

#### John H Hammond

The fascinating illustrated history of the original 'camera', an optical viewing instrument once widely used by astronomers, artists and entertainers, but now almost forgotten except by historians and collectors, by whom the early instruments are greatly prized. This chronicle of its long history is told through the writings of those who made or used the camera obscura for scientific or artistic purposes, and those authors who recorded its varied uses. The book is extensively illustrated with archival material, diagrams and photographs of surviving instruments. October  $xii + 182pp 255 \times 190mm 102$  illustrations hardcover 0-85274-451-X f13.50

# Colour Vision in the Nineteenth Century

The Young-Helmholtz-Maxwell Theory

#### Paul D Sherman

The intriguing, and previously untold, story of the chequered progress towards a fundamental understanding of colour perception and colour mixing, offering a new, and truer, perspective of the contributions and misconceptions of the many nineteenth-century physicists who became embroiled in the colour problem.

October xvi + 237pp 240 × 160mm 8 colour illustrations, 6 portraits, 51 diagrams hardcover 0-85274-376-9 £35.00

#### **A European Experiment**

The Launching of the JET Project

#### **Denis Willson**

A revealing account of the impact of national and supranational politics upon an international scientific collaboration. Denis Willson describes from personal experience the progress—and the discussions, disagreements and setbacks—in establishing a major fusion energy experiment, the Joint European Torus (JET), within the European Community. November  $x+178pp 220\times140mm 35$  illustrations hardcover 0-85274-543-5 £10.50 flexicover 0-85274-549-4 £6.95

# Applied Thermoluminescence Dosimetry

#### Edited by M Oberhofer and A Scharmann

Intended to become the new standard reference on TLD and its applications. The integrated multi-author text covers the theory, instrumentation, materials and methods of TLD, before discussing its wide-ranging applications in personal dosimetry and environmental monitoring, in medicine and biology, and in industry and archaeology.

and archaeology.

October xiv + 396pp 240 × 160mm illus hardcover 0-85274-544-3 £35.00

#### **Parallel Computers**

Architecture, Programming and Algorithms

#### R W Hockney and C R Jesshope

A practical and comprehensive introduction to one of the newest and most revolutionary fields in computer science. It explains the use of parallel architecture in operating supercomputers, and describes and compares several successful machines. Guidance is offered on the design and selection of parallel algorithms for a particular computer and on suitable programming languages for parallel applications. Circle No.23 on Reader Enquiry Card.

forting background of assumptions held in common with their readers. But they should at least try to be clear, at whatever cost to their credibility.

Dr Sheldrake writes as Mrs Bloom daydreamed, with no one theme rigorously explored before it sets off another which before resolution gives way to something else again. It would be unkind to suggest that this is a device for escaping from difficulties, but even readers who are wholly unsympathetic might welcome a clearer view of the author's position. For example, in discussing the limitations of morphic resonance he assumes that while past events can be effective now, future events cannot. While conceding that it is logically conceivable that they might be, he excludes the future on the ground of simplicity and remarks severely that "only if there were persuasive empirical evidence for a physical influence from future morphic events would it become necessary to take this possibility seriously". Apart from the ambiguity of introducing physical influences into a discussion of extraphysical phenomena, one is left wondering why the same severity is not applied to the past.

Indeed, Dr Sheldrake does believe that his ideas are capable of receiving support from experiment, but his proposals for experiments are curiously tentative and unsatisfactory. Thus

... if thousands of rats were trained to perform a new task in a laboratory in London, similar rats should learn to carry out the same task more quickly in laboratories everywhere else. If the speed of learning of rats in another laboratory, say in New York, were to be measured before and after the rats in London were trained, the rats tested on the second occasion should learn more quickly than those tested on the first.

Well, yes, but so they should without the London intervention, and any quantitative predictions in the operation of this hypothetical principle are so wholly arbitrary that the design of such experiments would be difficult indeed. Dr Sheldrake concedes this in his rather casual

Rupert Sheldrake — contribution to a happy state of confusion?

suggestions for a handful of investigations in each of which he describes a possible result *supporting* formative causation, but the opposite result is inconclusive. It would be a help if he could offer us predictions the failure of which would end the matter.

Anyone tempted to take formative causation or morphic resonance seriously should ask themselves why. A world haunted by messages from the past, some, like those from morphic units of extinct species, destined to vibrate eternally and in vain while seeking a morphic germ with which to resonate, may have a poetic appeal. Unfortunately it may also appeal to a perverse fear of scientific understanding. Dr Sheldrake explains early in the book

that while some outstanding biological problems are difficult, others are, in principle, insoluble — for example, those associated with evolution and with the origin of life. Neither, as it happens, is suitable for the operation of formative causation, since they are creative and unique rather than repetitive. But by the end of his exposition one reader had the distinct impression that intrinsic insolubility had its own attractions for him and that the hypothesis of formative causation was his contribution to a happy state of confusion.

D.R. Newth is Regius Professor of Zoology at the University of Glasgow.

# Selling newspapers and selling science

Eric Ashby

Reflections on Science and the Media. By June Goodfield. Pp.128. ISBN 0-87168-252-4. (American Association for the Advancement of Science: 1981.) \$9.

"JULES de Goncourt once wrote that . the newspaper bore the same relationship to a book as a whore did to a decent woman". A verdict, as June Goodfield says, "too harsh by far"; but as a caricature of the way some of the mass media deal with science it has an uncomfortable relevance. A news item is a one-night affair unless it attracts enough readers or the TV ratings to justify a follow up. As soon as the issue no longer stimulates the reader or the viewer it is dropped. Never mind that the issue is important, still unresolved and ought to be kept before the public: out it goes to make room for something more newsworthy. Of course there are honourable exceptions to this generalization, but as a rule news keeps no better than fish: indeed less well than fish, for fish can be put in cold store and still eaten with relish. News that has been put in store is worthless.

This is one of the reasons for the mutual suspicion between scientists and journalists. They work on different timescales. The scientist who publishes halfbaked findings loses the respect of his peers. The journalist who fails to publish his findings promptly, however half-baked they are, loses his job. And on the journey from the laboratory to the news-stand the information may get horribly distorted. The interview between journalist and scientist may have lasted an hour; the journalist has to chip away the reservations and complexities so that he can fit the story into half a column; the sub-editor (the worst culprit of all) slices chunks out of the journalist's copy and adds a sensational headline which must often sicken the journalist as well as infuriate the scientist who in good faith has explained his work.

And the outcome: a wider alienation between science and the media.

This didn't matter in the days before the public became the patrons of science. It would not matter today if everyone read the New Scientist or the science correspondents in the quality newspapers, or even watched science programmes on the BBC. But they don't, and they pay taxes some of which support science. What should they be told about science?

In the United States the presentation of science on TV is much less satisfactory than it is in Britain, and science in the massmedia newspapers is no better reported than it is in Britain. The only science that is "sold" to the public is likely to be scandalous (for example the thalidomide affair) or open to ominous speculations (genetic engineering) or fashionable (pollution, in the 1970s). What is urgently needed is a much better public understanding of what science is about, how it is done and what consequences it has for society. These are difficult matters to put across and there's no money to reward those who try to do it.

It was, therefore, an excellent idea for the American Association for the Advancement of Science to commission an essay on science and the media, and a brilliant choice to offer the commission to June Goodfield, who already has an international reputation for her interpretation of science to the so-called lay reader. With first hand experience in the two professions of journalism and science and a sympathetic understanding of the constraints under which both these professions work, she has offered a clear and in places refreshingly provocative analysis of the "uneasy relationship" (as she calls it) between the two professions.

She rejects the view (still held, alas! by some scientists) that the great bingoplaying, football pools, top-of-the-pops majority don't need to be told about

science and wouldn't understand it anyway. They do understand the science stories that do get into the mass media: if this were not so, the science stories would not appear there at all. But this does not mean that science reporting must be sensational. Members of Mechanics' Institutes in the nineteenth century responded with enthusiasm to the journalistic essays of Faraday. Readers of the tabloid press were enthusiastic about science reporting by J.B.S. Haldane in the 1920s. So, there is a strong case for science journalism at this very popular level to be accurate, enlightening and responsible. What constraints stand in the way?

For the mass circulation newspapers the constraints are that the news item must arouse immediate interest, it must be grasped at first reading, and it must have an element of novelty. (How close to the bone was the analogy of Jules de Goncourt!) If papers don't sell they go out of business. Released from these three constraints they would not sell.

For television news, as contrasted with sustained scientific programmes such as The Ascent of Man and Life on Earth, there are similar constraints. A Select Committee report (on hazardous wastes for instance) is published on a Tuesday. It is, let us say, 150 pages long. On Tuesday evening it will have to be reported "on the box", with a verdict on its merits or (preferably) its deficiencies, mustered that afternoon over the telephone. In Britain some of the sustained programmes are splendid. This is possible (as June Goodfield explains) because the producer is "totally responsible for the content and impact of the work". He doesn't have someone else in the hierarchy breathing down his neck all the time. In America it is otherwise; there "the long arm of sponsorship" reaches down even to the details of the production. Even public television, where there have been some successes, seems constrained to plug the wonders of science rather than the experience of doing science and the effects science is having on the way people live.

The scientist, too, works under constraints that block his contacts with the public. His peers, higher in the pecking order of distinction, are breathing down his neck: too much (or, just as bad, too successful) popularization, and the whisper "not altogether sound, you know" echoes in the academic groves. News is enlivened by human interest, so the media like a little autobiography to be brought into a science story (hence the success of James Watson's The Double Helix). But it is the aim of scientists at work to be self-effacing; they never publish their false starts, their failures, their own reactions to the research they do: all these are filtered out before the paper is sent to the learned journal to be published. The chief constraint is the necessity imposed by the conventions of scientific research not to reach premature conclusions, not to

advance to a position from which you may one day have to retreat, and never, never, in reporting research, to extrapolate beyond your data to broad speculations. If your research does have social consequences, discussion of these has to be put into different journals addressed to a different readership. This is one of the difficulties science reporters have to contend with.

June Goodfield illustrates the difficulties in the way of bringing journalists and scientists on to the same wavelength by four examples. There was the scramble of reporters to make a sensation out of the affair of Summerlin's painted mouse. In their haste to get a story out, all but one of them got the story wrong. Only one journalist, Gail McBride of the Journal of the American Medical Association, took the trouble to understand the whole story, and (of course) by the time she published, four months after the event, it was no longer news. Then there was the worldwide, and at times hysterical, publicity following the Asilomar conference on recombinant DNA. There was an even more hysterical exhibition over Rorvik's false claim about a cloned man, exposing the venality of a publisher who contrived to create a bestseller out of the phoney book. And there was the example of investigative iournalism at its best: the sustained campaign to expose the cover-up over thalidomide.

With great skill June Goodfield attempts a summing-up. Both scientist and journalist begin on common ground: it is their business to discover and to publish the truth. Neither profession has an explicit code of ethics, nor a controlling body which (like the General Medical Council) can deprive a practitioner of his right to practise. In science, peer opinion provides a crude, but on the whole effective, mode of control. Shoddy work is not condemned in bitchy articles, such as Leavis wrote about Snow; it simply sinks without trace.

In journalism the implicit code of ethics is weakened by a pervading hypocrisy. It is a scoop to publish a secret government document illegally obtained; it is also a scoop to expose someone outside the profession who has obtained a secret document for his own ends. A contractor who bribes a politician is fair game for publicity, but not a journalist who bribes a witness. June Goodfield wants journalists to tighten their code of ethics but she would like them also to assume some responsibility to act as critics of the ethical implications of science. The need for this arises because scientists do not have a cloud of critics hovering round them, as novelists and dramatists have, and they deliberately dissociate their work from its ethical overtones.

As for the scientists, she wants them to take the trouble to sympathize with the constraints under which journalists have to work, to be less arrogant and more co-

operative, to realize that journalists are an essential channel of communication between themselves and the public on whom they depend for a livelihood. She wants devices for disseminating information in suitable form to the media. She wants the interpretation and communication of science to be taken more seriously as disciplines in universities, so that a student could find training for science-writing.

Her main suggestion is that there should be critics in science who play roles like those played by critics in music, literature and the arts, critics "in the accepted, oldfashioned meaning of the term". This is the one point in June Goodfield's essay with which I disagree: for two reasons. First, the achievements of science are published normally as papers in journals, not as books. (For books there is a mild critical apparatus already, e.g. in the review columns of Nature and other science magazines.) Second, the scientific content of research papers is effectively criticized by the use made of the papers by other scientists. Research of high quality is quoted. Research of poor quality is disregarded. So I see no merit in having professional science critics. If all critics were like Walter Lippmann or Edmund Wilson or Donald Tovey, that would be fine. But critics now abound like carrion flies, swarming over the work of people engaged in the desperately difficult professions of literature and art, dismissing, with a patronizing drawl, such as one hears on some radio programmes. creative work they would be quite incapable of doing themselves. God preserve us from critics like that in science. Nor will they be needed while there are scientists about who have June Goodfield's brilliant capacity to work at the interface between science and the humanities

Lord Ashby is Chancellor of Queen's University, Belfast, and a Fellow of Clare College, Cambridge.

## The measure of man

P.B. Medawar

A History of the Study of Human Growth. By J.M. Tanner. Pp.499. ISBN 0-521-22488-8. (Cambridge University Press: 1981.) £30, \$69.

PROFESSOR Tanner has made important contributions to the practice and methodology of anthropometry; one thinks especially of his studies of secular changes in human growth rates and in landmarks such as age of onset of sexual maturity in the two sexes. He is well known also for his advocacy of the cohort method in the analysis of human growth (the "longitudinal" method as opposed to the more familiar "cross-sectional" method

which has the disadvantage that curves of growth tend always to be confused by curves of distribution).

It is not usual for practitioners of a science to write of its history, but if it comes off, as it does here, the result is a triumph. Tanner could hardly do otherwise than begin with the voluminous and in the main tiresome works by or attributed to Aristotle: instead of calling attention to his more egregious and least easily explicable blunders, such as the belief that human semen is infertile until the age of 21, Tanner makes the best of Aristotle by finding grounds for the neat and convincing inference that "in 350 BC children were maturing at approximately the same rate as now".

Among Tanner's most interesting passages are those that deal with the hebdomadal tradition: the number-magic that found expression in the belief that the body is divided into seven parts and the life of man into seven stages each seven years long.

The mystique attached to the seven-fold system makes reliance on the truth of any actual age impossible however; both at the time and for centuries later there is a tendency for all ages to be rounded to the nearest hebdomadal number.

Tanner is a learned and widely read man, and his book is full of fascinating historical and sociological insights:

... the growth of children of the manual labouring classes in England in the 1830s, and even the 1870s, was still more depressed than that of the poorer groups in some of the underdeveloped countries nowadays ... we should not be too surprised. Indeed children of slaves in the plantations of the southern states of America at this time ... were taller (by some 2 to 5 cm) than contemporary children of manual abourers in England (although nowadays the heights of children of European and of African descent living under similar economic circumstances are almost identical).

Tanner devotes some amusing paragraphs to passages from J.J. Virey ("that would have done credit to Baden Powell") professing to demonstrate the debilitating effects of masturbation. J.J. Virey (1775–1846) was a pharmacist who contributed to the Dictionnaire des Sciences Médicale.

Although the book is mainly about human growth, Tanner casts a wider net and manages to make mention of D'Arcy Thompson, who had little to say about human growth. As an admirer of D'Arcy's, I can vouch that Tanner's placing and appraisal of him are exactly right — "a late flower of the Renaissance" who wrote superlative prose.

This is an excellent book which may be read with advantage by all biologists interested in the history of ideas — and should certainly be read by sociologists and social historians as well.

Sir Peter Medawar is Head of the Transplantation Biology Section at the Medical Research Council's Clinical Research Centre, Harrow, Middlesex.

## Education in science, science in education

Nevill Mott

Science in Schools: Which Way Now? By Richard Ingle and Arthur Jennings. Pp.185. ISBN pbk 0-85473-100-8. (University of London Institute of Education/NFER-Nelson: 1981.) £5.30.

THE authors of this book give an account of what has been happening in science education in the UK and of what, in their opinion, ought to happen now. One of them graduated in physical sciences, the other in biology; both had considerable experience of school teaching before moving into the field of teacher training and educational research. The emphasis of their book is on "science for all" and it gives as clear a discussion as any I have seen of the objectives to be achieved by giving all children, up to the age of 16, considerable time for science. What the authors discuss rather little, in that they do not present it as a separate problem, are the needs of that minority who after further education are going to make use of their science, as engineers, technicians, research scientists and doctors.

The rise of general science in the interests of science for all, and its subsequent decline up to the time of the change to comprehensive education, is described here, as it is perhaps more fully in the chapter "The General Science Movement" in E.W. Jenkins's book From Armstrong to Nuffield (John Murray, 1979). In the years between the two wars, Ingle and Jennings say that the move towards general science was based on the notion that science should be for everyone, not just for the embryonic professional scientists (which presumably includes engineers, doctors and others), and that it should form an essential part of the general education of all young people. But in practice, they add, general science was found to be "a scrappy mixture of physics, chemistry and biology". Certainly, in the immediate pre- and postwar periods it enjoyed little prestige as a university subject, in comparison with the specialist honours degrees. Moreover in the post-war period, policy-makers, conscious of the role of science in the war and of the perceived need for qualified scientists and engineers (OSEs) in industry, had little use for general science. Two authorities, quoted by Jenkins (p.99) wrote that

An improvement in . . . school science teaching is a requirement for the continued existence of this country as a leading scientific and industrial nation. As a first step in this direction general science should be abandoned.

Ingle and Jennings report that in the 1950s, in independent and grammar schools, general science was declining fast and two or three specialist O-levels were the norm. However, in the secondary modern schools, they say, teacher training colleges serving them were sufficiently independent

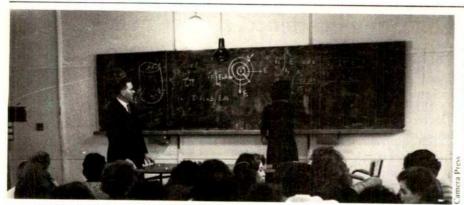

from universities to help teachers make the science more child-centred and less academic than in grammar schools. Unfortunately these teachers were rarely encouraged to publish their methods, "so that their experience and wisdom died with them".

A second chapter deals with "the curriculum development era", starting in 1960, and particularly the Nuffield Science Teaching Project, beginning in 1961-1962. This aimed to produce material in the three separate sciences, initially in the age group 11-16, for children in the selective grammar schools, and equally suitable for both future science specialists and others. In all three projects it was the aim that children would learn science largely through experimental enquiry, with the guidance and support of the teacher. The reception of Nuffield in the schools is described, as is its influence even in schools where the whole package was not accepted. Two criticisms of the original Nuffield scheme have been that the work was very demanding, even for the more able pupils, and that neither the O-level nor A-level schemes went far in illustrating the social relevance of science. Later projects for the less able child are described, including Nuffield Science 13-16 (now being published), the Association for Science Education's (ASE) project for "Less Academically Motivated Pupils" (LAMP), and also the much more demanding Schools Council's Integrated Science Project (SCISP), which with a time-table allocation equivalent to that for two O-levels brings together the three sciences with time for ample attention to be paid to their social aspects. Also described is the Schools Council's Project Technology, which had the aim of helping pupils to understand the importance of engineering in our way of life. In spite of the expenditure of £300,000, this project, they say, has had little impact; perhaps this is because science teachers teach best what they know best, and very few science teachers have been trained as engineers. In this context, the authors include an apposite quotation from B. Prescott:

Perhaps one of the greatest weaknesses of science teaching is that it is science teachers who do it — science teachers who have been initiated into the profession by science teachers and they teach courses written by scientists and science teachers.

But if this is a weakness, how is it to be corrected?

In chapters on aims and ideals in science education, and on hopes for the future, Ingle and Jennings identify themselves with the swing back towards general science and science for all, and away from the objective of producing QSEs, a movement which has undoubtedly taken place in the last decade. Reasons for this

Physics for sixth-formers — in the 1980s will they receive the grounding they need?

are perhaps the introduction of comprehensive schools, the unfavourable image that science and technology has sometimes presented and a widespread reaction against the so-called elitism of conventional scientific education. An extreme example of this reaction was the issue by the ASE of its discussion document "Alternatives for Science Education" (1979) which two years ago sent a shock wave of dissent through more conservative circles.

In this document it was claimed that science education as it is now is elitist, designed for the minority intending to make a career in science and against the interests of the majority. Alternatives were suggested, some of which seemed to propose teaching more about the role of science in the modern world than the practice of science itself. The ASE's most recent document, "Education through Science", issued in August 1981, puts forward a more moderate policy for the future which does not differ much from the proposals in the book under review, and which indeed carries widespread support. It is proposed that in all schools for children between 11 and 16, one-sixth of school time should be spent on science this would correspond to the time spent on two O-levels - and that integrated courses including physics, chemistry and biology, tit-bits of other sciences and coverage of social implications would be devised. This, it is claimed, would avoid irrevocable choices at 13, which so often cut children and particularly girls off from careers in science and its applications. Also it would avoid the lack of balance between science and the humanities which the study of three separate science subjects is said to involve.

Thus science education, as mapped out in this book, should be intended for all children. Rather than summarizing the aims set forth by the authors, the flavour of their argument may be given by the following quotation from a CSE project report which they include in the book:

My project worked very well and I'm pleased because (i) I got alcohol from paper which I thorught was never possible, (ii) because I used some new aquipment which I've never herd of let alone worked with. Another thing I was pleased about was there was lots of experiments and if there was anything I wanted to know there was

book's at my finger tips so there wern't any time lost. If I had a lot more time what I would like to make is a lot more alcohol and do lots of flame tests because I only made about Icm<sup>3</sup> of pure alcohol. So I could not do much, I would allso like to find how much yeast is necessary to ferment it propley yet let the alcohol burn propley. I would also like to know if it was the yeast that stopped it burning. I would also like to learn how to control the heat when distilling because that a mistake I made.

Curiosity, ability to think and to form ideas of what science and technology are about are to be emphasized. The authors recognize that "there are many young people who will leave school to seek employment in some field of science and technology, and that these will need a more extensive knowledge of science". Reference is made to "the more demanding courses that may be necessary to engage their minds and prepare them for sixth form studies". The italics are mine. Little discussion is devoted to the vexed question of setting or streaming for these more demanding classes. The authors give the impression that, although they realize that setting in science subjects (or avoidance of science by the less talented) is almost universal, at any rate from 14 to 16, they hope that mixed ability teaching will spread. But this book does at least recognize the needs of the talented.

Two years ago the Education Committee of the Royal Society issued a discussion paper entitled "Science and the Organization of Schools in England; Implications for the Needs of Talented Children" Here it was taken for granted that setting for science and mathematics was in the interests of talented children, that they needed to be with children of like ability and to make progress at their own rate. The fear was expressed that in small comprehensive schools, particularly if falling rolls should make them still smaller, there would not be enough children to form an O-level class. It also defended the retention of three O-levels together with a choice of subject, among other reasons because teachers can teach best what they know thoroughly. It is true that almost any reform is bad if it does not increase the teacher's confidence in his mastery of his subject; for this reason Ingle and Jennings rightly stress the need for in-service training, preferably school based.

If school education goes the way recommended by Ingle and Jennings, we can envisage a future as follows. All children will spend one-sixth of their time on science up to the age of 16. There will be a common examination system, unifying CSE and O-level, but separate questions or even papers of appropriate difficulty may be set. The separate teaching of physics and the other subjects may disappear, except perhaps in the independent sector. There will be a common core; the lower ability groups will not have vague talk about science fobbed off on them but will be exposed to some real science. Ideas on the teaching of the less talented will develop, and some success is expected. Setting, however, is likely to remain. The experience with SCISP shows that talented children who have done the equivalent of two O-levels do not have difficulty with A-levels as they now are. Whether more science teachers able and willing to teach all three sciences will be found, only the future will show.

We have here a way forward which, I believe, may well be in the interests of the average child and also of the more talented child who does not want to specialize in science. But for future scientists, I have doubts. Probably a wider education, cutting down in the time spent on science up to the age of 16, will not do them any harm. On the other hand, if they are held back, and not allowed to progress as fast as they can, they may become disillusioned and even give up the subject. How much do we want to keep the most talented back, in the interests of the majority, or of general education or for any other reason?

If the authors of this book do not see this as a major problem, they have much of interest to say on many other matters. One is the need for collaboration between the teachers of science and of mathematics; another, perhaps more original, is the help that historians ought to give in teaching the history of science. Another is the value of education in science towards learning to express oneself clearly. Finally, the authors quote Richard Peters as writing (in 1972) that "our state of ignorance with regard to teaching is comparable to that of the Greeks with regard to medicine or meteorology". Ingle and Jennings end their book by expressing the hope that systematic school-based research will hasten the day when science teaching, while remaining an art, will become more of a science. And as a consequence, they hope, as we all must, "that the promotion of teachers might then begin to depend less on confidential references and more on soundly based competencies".

Sir Nevill Mott was Cavendish Professor of Physics until his retirement. He was a member of the Crowther Committee on education from 16 to 18, and has chaired various advisory committees for the Ministry of Education and for the Nuffield School Science Project. He is now a member of the Royal Society's Education Committee.

# **Gyrotropic Waveguides**

Paul Hlawiczka

December 1981/January 1982, x + 96pp. 0.12.349940.2 £12.80 (UK only)/\$26.50

The book includes discussions of the gyrotropic medium followed by various configurations of the gyrotropic waveguides and ends with a brief survey of the application possibilities at optical wavelengths at the time of writing. *Gytropic Waveguides* should therefore prove stimulating to research workers in optical communications and integrated optics, although it should also appeal to other scientists inerested in guided waves

# Multivariable and **Optimal Systems**

D.H. Owens

October/November 1981, x + 300pp. Cloth: £22.80 (UK only)/\$47.00 0. Paperback: £8.00 (UK only)/\$16.50 0.12.531720.4 0.12.531722.0

Most of the material published here is presented at a high level with emphasis on generality and mathematical rigour, yet the underlying concepts are essentially simple and the most applicable parts of the theory can be understood without using sophisticated mathematics. This text aims to provide a comprehensive, up-to-date and consistent treatment of the minimal foundations of those parts of the field with greatest relevance to practical design work. It enables the reader to tackle working design examples and lays the conceptual foundations for further study. All this is done using only undergraduate engineering mathematics.

## Stability and Reactivity of Crown-Ether Complexes

F. De Jong and D.N. Reinhoudt

October/November 1981, vii + 164pp. £12.80 (UK only)/\$31.00, 0.12.208780.1

This is the first of a new sequence of occasional reprint chapters extracted from the Advances in Physical Organic Chemistry series. Predominantly paperbound and priced inexpensively for the individual purchaser, they will give the specialist rapid access to selected articles of particular interest.

This book presents a critical evaluation of the physical organic chemistry of crown-ether complexes with organic and inorganic guest molecules. By analysing the parameters that influence the thermodynamic and kinetic stabilities, the reactivity, chiral recognition by chiral crown-ethers, and enzyme-type of catalysis, the authors draw some general conclusions about this subject.

# The Downy Mildews

edited by D.M. Spencer

October/November 1981, xxii + 636pp., £49.60 (UK only)/\$119.50 1.12.656860.X

The aim of the book is to present an integrated and authoritative statement of our present knowledge of the downy mildews. It is in two parts and the first chapters provide general reviews of the history, taxonomy, distribution, epedemiology, host range, genetics, breeding for resistance, host-parasite relations and control of the downy mildews. The second part then deals with the downy mildews of individual crops or commodity groups.

## **Blackflies**

The future for biological methods in integrated control

edited by Marshall Laird

October/November 1981, xii + 346pp., £28.20 (UK only)/\$58.00 0.12.434060.\$ £28.20 (UK only)/\$58.00

Leading specialists in all fields connected with the description of and solution to the blackfly problem have contributed to this book; classification, zoogeography, ecology and physiology are all examined. It is a comprehensive reference work on the background and control of blackflies, and it also provides a thorough description and appraisal of the most up-to-date discoveries and ideas on biocontrol.

# Advances in Parasitology

edited by W.H.R. Lumsden (Senior Editor), R. Muller and J.R. Baker

October/November 1981, x + 226pp., £16.40 (UK only)/\$39.50 0.12.031719.2

This long-running series has gained a reputation for its detailed and original reviews on a variety of subjects within the field of parasitology, Volume 19, the latest in the series, deals with three groups of parasites — which are not commonly dealt with in review articles. The present editors have broadened their policy to admit for review any group of organisms whose members follow the parasitic mode of life, emphasizing areas of parasitology which have advanced significantly at the time of writing.

## Genetic Consequences of Man-Made Change

edited by J.A. Bishop and L.M. Cook

# **EVOLUTION** FROM SPACE

FRED HOYLE AND CHANDRA WICKRAMASINGHE

In this very important sequel to their highly successful Lifecloud and Diseases from Space, the authors turn their attention to evolution and put forward a sensational new theory that revolutionizes our understanding of the evolutionary process. They argue that major new changes of species arise not by Darwinian processes – mutations and natural selection – but by the introduction of cosmic genes into already existing life forms, and that the exceedingly intricate complexity of life at a molecular level points to the hand of a creator.

# The eighteenth-century generation game

Christopher Lawrence

Matter, Life and Generation: Eighteenthcentury Embryology and the Haller-Wolff Debate. By Shirley A. Roe. Pp.214. ISBN 0-521-23540-5. (Cambridge University Press: 1981.) £16, \$32.50.

AT FIRST sight the eighteenth-century debate on the nature of generation and embryological development might appear to have been a parochial affair. The path from fertilization to birth, however, was by no means a simple scientific conundrum calling for a straightforward empirical enquiry. As Professor Roe displays so clearly in this excellent book, generation was a hinge on which turned alternative cosmologies. Different theories of development brought into conflict incommensurable universes. Professor Roe has therefore used this particular study as a case history to illustrate some more general philosophical points about the nature of scientific enquiry and explanation.

In the eighteenth century there were two possible views on generation which were scientifically respectable. Preformationists held that embryos pre-existed in either the semen or the egg and these embryos in turn, like a nest of dolls, contained intact the next generation in their germinal material, and so on. This theory, first fully articulated by Malebranche in 1674, had considerable advantages over its rivals. The scientific revolution had virtually swept the intellectual field by the late seventeenth century. It left behind only matter, motion and — after Newton — force as the fund-amental explanatory principles in the cosmos. Preformationism therefore explained the puzzle of why it was that the embryo developed in the way it did, rather than crediting the possibility that matter in motion could somehow give rise to organized material.

This latter eventuality was embraced by the epigenesists, who held that the embryo developed form and parts from where there

Chicken development — detail from Fabricius's De Formatione Ovi et Pulli (Opera Physica Anatomica, 1625).

had been neither form nor parts before. The most famous epigenesists of the eighteenth century were Maupertuis, Buffon and Needham, and in the world of belles-lettres the philosopher Denis Diderot. All of these thinkers circumvented the problem of formal development by postulating that matter was innately active and not the passive servant of other forces. The preformation -epigenesis dichotomy therefore was not a simple scientific schism. Rather, on the one hand lay the divinely formed embryo, special creation, a meaningful universe, and thus a Christian cosmology and salvation. With epigenetic development lay chance, purposelessness, Lucretianism and extinction.

In the middle of the eighteenth century this debate was rekindled by the pious, Newtonian, Professor of Anatomy at Gottingen, Albrecht von Haller and the rationalist, upstart physician, Caspar Friedrich Wolff. Haller espoused preformationism and Wolff epigenesis, and for ten years they discussed the issue in print and in private correspondence. Two factors make the debate particularly interesting. First, they both conducted a great deal of detailed empirical research on the development of the hen's egg, attempting to discover or refute whether the chicken came first so to speak. The debate thus turned on complex technical questions such as the appearance of the heart, the gut membranes or the yolk sac vessels. Second, Wolff was no ranting atheist. Rather, he too was a deeply pious Christian, but one who had begun with his feet in quite different metaphysical starting blocks to those of Haller. For Wolff, the laws of motion observed by matter had been created by God in the first place. Thus, epigenetic development was, in a way, preformationism one stage back.

Professor Roe unfurls this dialogue, or rather these two monologues, and shows clearly that, given the metaphysical corners of the protagonists, neither was going to get near enough to strike a blow. Where Wolff saw a heart developing and new bits forming, Haller saw a previously transparent structure becoming denser, coloured and demarcated from its surroundings. Professor Roe reveals these aspects of the debate with faultless precision founded on superb scholarship.

What is disapppointing, however, is that she stops short at either end of the argument. At the observational end she offers no discussion as to whether Haller and Wolff were interpreting differently the same data or whether they were actually seeing the world differently. Professor Roe never says whether Haller ever disagreed with Wolff's embryological drawings and denied that they represented reality, or whether Haller only disputed the meaning

of agreed observations. Neither is it clear whether Haller produced any drawings of what he saw. At the metaphysical end of the argument, Professor Roe seems to suggest her task is over when she has related a scientific debate to more general metaphysical principles. Having shown that the world rests on the back of an elephant, she neither asks if the elephant itself rests on anything or, if not, shows why her explanation of the Haller-Wolff debate might be sufficient once the metaphysics have been invoked. The epigenesispreformationism debate is therefore still a somewhat circumscribed area in eighteenth-century science. After this book, however, historians will need to perambulate a much extended perimeter fence.

Christopher Lawrence is Historian to the Wellcome Museum of the History of Medicine, London.

#### Battle over bacteria

G.D. Heathcote

The Fischer-Smith Controversy: Are There Bacteria! Diseases of Plants? Phytopathological Classic No.13. Translated and prepared by C. Lee Campbell. Pp.65. ISBN 0-89054-014-4. (American Phytopathological Society, 3340 Pilot Knob Rd, St Paul, Minnesota: 1981.) \$8.50.

PROBABLY few plant pathologists will make the time to read this pamphlet, which consists of little more than seven review papers published in Germany between 1897 and 1901, but the American Phytopathological Society did well to publish it. Perhaps they did so because it has a plot which could not fail to appeal to the American spirit. It tells how Erwin Smith, originally a poor farm boy from Michigan, battled (with words only of course) against the academic might of the classically trained Alfred Fischer, once an unsalaried lecturer in botany at the University of Leipzig, at the time when plant pathology was almost a German science.

The debate as to whether or not bacteria can be the direct cause of disease in plants stimulated the two protagonists into making bitter and personal attacks against each other. Smith's statement regarding part of one of Fischer's lectures: "It is seldom in a genuinely scientific book that one finds so many unwarranted assumptions and serious misstatements in the space of a single page ..." would undoubtedly have infuriated Fischer, and attacking Smith he wrote: "... after experiments of that kind ... no one will think badly of me that I had not sought further statements in the American

literature when I wrote my lecture".

Fischer was convinced that bacteria are only saprophytic upon tissues already broken down and that they cannot penetrate undamaged cells. Smith quoted experiments showing how bacteria can dissolve cell walls and that they can enter undamaged tissues, for example pear blight bacteria can penetrate through nectaries. In the end nobody won as such. Smith died in 1927 after a long and distinguished career, and although Fischer eventually suffered from depression and committed suicide in 1913 his professional stature was not diminished by the controversy.

Erwin Smith, farm boy turned plant pathologist. In 1899 he wrote of Fischer "...he garbles and misrepresents, charging other men with being stupid blunderers ...".

Nonetheless, the debate proved to be a significant event in plant pathology. Smith's view became accepted, and plant pathologists began to work seriously on bacterial diseases. Today between 180 and 200 species of plant pathogenic bacteria are recognized, causing serious economic loss throughout the world. They are unable to penetrate the plant cuticle and many require wounds to gain entry into the host plant but some enter through natural openings. Many are windblown or disseminated by splashing water, and at least 60 species can be carried by insects, for example fire blight of apples and related species is carried by honey bees.

The statements some of us make today are usually shorter but they are no more reasonable than those made by our predecessors. I can well remember the disbelief when it was first suggested that nematodes can carry virus diseases, and some of the diseases I thought to be caused by the viruses have been shown to be caused by mycoplasma-like organisms. Like so many controversies of the past, the Fischer-Smith debate repeats the lesson that in plant pathology, as in all of science, dogmatism is dangerous.

# Test tube to womb: ethics and politics

R.V. Short

From Chance to Purpose: An Appraisal of External Human Fertilization. By Clifford Grobstein. Pp.207. ISBN 0-201-04585-0. (Addison-Wesley: 1981.) \$17.50, £11.50.

In this book Dr Grobstein, Professor of Biological Science and Public Policy at the University of California, San Diego, seeks to describe for the general reader the technical procedures involved in human in vitro fertilization, and the social and political implications of this work. We are told that Dr Grobstein is internationally known for his research in developmental biology, and so we are entitled to expect a good read, and a penetrating analysis of present developments and future prospects.

The book turns out to be little more than an annotated commentary on the report of the US Ethics Advisory Board on Research Involving Human In Vitro Fertilization and Embryo Transfer, which was published in 1979. Fortunately this report is reprinted as an appendix, and for those not already familiar with it, it will form by far the most interesting part of Grobstein's book. Joseph Califano, the former Secretary of Health, Education and Welfare in the Carter administration, deserves considerable credit for setting up the Ethics Advisory Board, alas now disbanded, and charging such a distinguished group of scientists, lawyers, theologians, clinicians, ethicists and administrators with an in-depth investigation of the whole subject of in vitro fertilization. The way the Board went about this task was commendable. They commissioned manuscripts from leading experts known to have views on the matter, and held public hearings around the United States, with live radio and television coverage, to which anyone could give testimony, and at which the experts were cross-questioned by the Board. All the written evidence was then published, together with the incisive, common-sense judgements of the Board, who must have been greatly indebted to their chairman, a lawyer, James C. Gaither, for producing a consensus report from a Board that itself embraced such widely divergent views. The conclusions were neither remarkable nor controversial. The human embryo is entitled to profound respect, but this does not necessarily encompass the full legal and moral rights attributed to an adult individual. Therefore, a broad prohibition of research involving human in vitro fertilization is neither justified nor wise. Federal support for such work would be ethically acceptable, and there is a need for more research in order to assess the risks to mother and offspring.

The Board managed to steer a course between the Scylla of those such as the President of the Massachusetts Council of

Rabbis, who thundered that "Further in vitro experimentation could tend to eliminate the need for the human family and turn humanity into a zoo of fertilized and fertilizing animals", and the Charybdis of the brothers Seed (sic) who offered to buy fertilized eggs flushed from the uteri of women donors, and transfer them to the uteri of infertile recipients - at a price. Nevertheless, the publication of the Board's findings in the Federal Register on June 19th 1979 produced a storm of written protest from, one suspects, the Right to Life group. Secretary Califano took no action on the Report's recommendations, and shortly thereafter resigned. The Ethics Advisory Board was then disbanded because Congress established a new "President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research" that does not seem to have addressed itself to the problem, and America changed Presidents.

Since that time, nothing more has been heard of the Board's report. It seems to have sunk without trace, presumably too hot for a right-wing administration to handle. But thereby went an honest attempt to reach a consensus view by public debate of a contentious issue, and much time and money was wasted in the process. It is sobering for scientists to realize that even if an issue is scientifically, socially and ethically acceptable, it will receive no governmental support unless it is politically expedient. But Everyman will have the last say; new clinics are opening up around the world, and the number of successful births following in vitro fertilization is now into the teens. Even the President of the United States cannot halt such progress, although the paucity of governmental funding for the back-up research that is so urgently needed can significantly delay it. The success rate of the procedure is still very low, and research could surely improve it to the point where we might expect a 25 per cent chance of pregnancy following embryo transfer, which is the probability that a fertile woman has of conceiving in an ordinary menstrual cycle.

But all of these comments relate to the appendix. What of the book itself? It has little to add that is new, much that could have been discussed is missing, and several statements are factually incorrect. As for its good points, it is sensible to suggest that we should re-name in vitro fertilization "external fertilization", a term that is infinitely preferable to "test-tube baby", which has alas probably come to stay. Grobstein also has an interesting chapter on "Becoming a Person", in which he propounds the common-sense view that "neither life nor the human quality begins in any generation. Human life, like that of all species, descends without break from

G.D. Heathcote is at Broom's Barn Experimental Station, Higham, Bury St Edmunds, Suffolk.

generation to generation. It waxes and wanes in complexity but never begins de novo". But he has an ungainly style of writing: talking of human attributes, he says "As a group they span the biological, behavioral, and social realms, constituting a kind of slope between animal and human states along which our species has moved evolutionarily and continues to cycle generationally'

Although there is much discussion about "circumventing the oviduct", a valuable opportunity is missed by failing to compare this with "circumventing the penis"; the ethics of artificial insemination, whether by donor or husband's semen, have been widely discussed in recent decades. On the technical side, it is disappointing to find no mention of ultrasound, which is now widely used as a non-invasive way of monitoring follicular development. There is no discussion of interspecific fertilization, and yet use of denuded hamster oocytes to bioassay the fertilizing capacity and examine the karyotype of human spermatozoa has been an exciting recent technical advance seems to send an ethical the World Health Organiz

### **Lessons for twentieth-century nutritionists**

John Rivers

Nutrition and Nutritional Diseases: The Evolution of Concepts. By Karl Y. Guggenheim. Pp.378. ISBN 0-669-03950-0. (Collamore Press, Massachusetts: 1981.) \$21.95.

ALTHOUGH this is an important book, it must be admitted at the outset that it is not a historian's history. Professional historians of science will no doubt be irritated by the brevity with which many subjects are necessarily treated and by the occasional lapses that suggest historical naivety (for example, calling Boyle's school "Eaton", or seeming to equate Pereira's training as an apothecary with pharmacy not medicine).

But whatever its reception by historians, nutritionists will I hope buy and read this book, for it is an important history of their discipline and their profession, and one that they should study. It is all the more valuable because Professor Guggenheim is not a trained historian, but a nutritionist who, after a lifetime of research into the practical problems of nutrition, has produced this scholarly work in his retirement.

The discipline of nutrition is an uneasy coalition. Its scientific roots are in aspects of physiology which had their heyday in the nineteenth and the first half of the twentieth centuries. Its justification is a wide spectrum of unresolved practical problems, from tooth decay to the world food problem. And nutritionists, it must be admitted, are people who, by and large, fail either to revive the science or solve the

problems to which it is addressed. As long as it is possible to imagine that, even if the next experiment won't save the starving masses at a stroke, it is a step in that direction, then there is an excuse for surfing along on the wave-front of the present. But as it increasingly appears that poverty not protein is the key to malnutrition, and that tooth decay can only be cured by drawing the teeth of the confectionery industry, the nutritionist increasingly needs to take stock and decide whether he is really necessary.

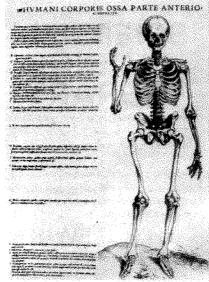

Individual action is of course irrelevant. What is needed is a dialogue within and beyond the profession about the extent to which nutritional science should be coupled to practical policy. Such a discussion would need to be guided by a coherent view of the past, and without the historian's spotlight can probably never begin. It is self-evident that such historical studies on nutrition as exist at present have not had any such catalytic role - not surprisingly, for where they are not social histories of diet, they are catalogues of achievements of the great and famous.

The significance of Professor Guggenheim's new book is that it is free of that tradition and hopefully will have a powerful impact. He does not merely retell the story of the development of the science of nutrition, but, more than any other work on the subject, he studies its growth mechanisms. His avowed aim is contained in the subtitle — he tries to trace "the evolution of concepts". He does so with great fluency, and in a way that is

realistic, in that it sees the concept as dominating the fact. Moreover, he makes his account relevant to today's problems by devoting a large part of the book to focusing "attention on the conceptual evolution of five principal issues that . . . dominate nutritional thinking until our own time". In doing so he has chosen well, and his discussions on the concept of an adequate diet, on protein and on the origins of the dietary thermogenesis controversy (recently revived in Nature) are all very valuable.

I am slightly disappointed by the fact that, inasmuch as he looks beyond internal imperatives for the growth of nutritional science, his horizon is the parallel growth of ideas in other areas of science. Highlighting this feedback is valuable, and he provides the best discussion of such interactions that is available in a popular work. But it is a pity that he did not extend his view and concentrate more on general social history and the extent to which nutritional science was also moulded by the general ethos of the society in which it was developed. In his failure to do so, his work raises questions it cannot answer. For example, his treatment of the evolution of concepts of protein and energy metabolism in the nineteenth century, while meticulous and well worth reading, is for me incomplete. I cannot believe that the subject can be fally explored without discussion of the social values that predicted it, stimulated both the research and its acceptance, and dictated its conceptual framework. Nutrition developed in the new Europe where both workhouse and standing army grew up, and the state required dietetic advice on subsistence requirements for the poor, and optimal provision for its fighting men.

It is surely no coincidence that in this environment nutritionists adopted models which involved the idea that both minimal

Skeleton of a rachitic male, depicted by A. Vesalius in Tabulae Anatomicae Sex (1538). Rickets was apparently so prevalent that Vesalius regarded the skeleton, of an adult with late rickets, as normal.

### Hectares for whom?

John Andrews

Farming and Wildlife. By Kenneth Mellanby. Pp.178. ISBN 0-00-219239-X. (Collins: 1981.) £9.50. Countryside Conservation: The Protection and Management of Amenity Ecosystems. By Bryn Green. Pp.249. ISBN hbk 0-04-719001-9; ISBN pbk 0-04-719002-7. (George Allen & Unwin: 1981.) Hbk £13, \$35; pbk £6.95, \$17.95.

SINCE prehistoric times, agriculture has been the major modifier of the world's terrestrial habitats: even the marine environment has been affected by the run-off of silt, organic nutrients and latterly of agrochemicals. In those countries where there is an active nature conservation lobby, relations with farming interests have become progressively more strained over the past 30 years as modern agricultural techniques have made rapid inroads into wildlife communities which had long coexisted with traditional farming methods. Inevitably, both sides have tended to misrepresent the situation to some degree and Professor Kenneth Mellanby's Farming and Wildlife provides a valuably calm and dispassionate appraisal of the effects of each on the other.

The opening chapters of the work deal in general terms with the impact of man on Britain's natural habitats and wildlife over the last 7,000 years, and more specifically with the effects of changing methods in arable farming, grassland management and livestock production since 1945. Greatly increased productivity from existing farmland has been won at the expense of a vast reduction in the population of until recently common and widespread wildlife, of which our native flowers and butterflies are perhaps the most regretted loss. At the same time, the profitability of farming and the incentives of grant aid have brought much marginal land into intensive production, severely reducing many species which were already rare. The middle section of the book looks in some detail at the features of typical lowland farms over which most public concern has been expressed — the soil itself; hedges and trees; and ponds, rivers and marshes.

Thus far the book contains much that will come as news to farmers who are often profoundly ignorant about the wildlife on the land and their own effects on it. By contrast, the final section contains much to inform the concerned but often equally ill-informed public about pests and pesticides, diseases of livestock and about field sports, which indirectly contribute to the retention of habitats and hence of wildlife in the countryside.

Farming and Wildlife is well illustrated and readable. No doubt conservationists will read it. The question is, will farmers?

Professor Mellanby deliberately eschews the political aspects of farming and wild-life, in particular the questions of whether increased agricultural output is economically justified and whether society should be able to control rural land use change where public loss of amenity is significant. However, these questions are examined with skill and relish by Bryn Green in Countryside Conservation.

It is timely that conservation, which has become an increasingly complex and skilled profession, now has its first text-book, and entirely apposite, given that the conservation movement is fighting desperately for what it believes in, that the text-book should also be a confident and well-argued assertion of its case.

Part 1 is devoted to conservation concepts, the impact of man on his environment and the development of conservation in Britain. In Part 2 the author examines the characteristics of natural ecosystems and explains the impact of land use change on all our major habitat types: agriculture figures largely, but forestry, industrial and urban development, recreational impact and pollution are given comparably thorough coverage. Conservation considerations aside, one is reminded again that land use management in Britain, where every hectare counts, is in appalling disarray, with blinkered state agencies each pursuing its own special interest regardless of the general good.

The concluding section of the book examines the present methods for selection and protection of land of conservation importance, and argues that a new approach is required if we are to save the remaining areas of scientific importance and the natural beauty of the countryside.

A welcome departure from the somewhat petulant "smocks and wind-mills" approach of some recent writers, Bryn Green's book contains much to instruct and to inspire a hard-headed approach to the massive problems which the conservation movement now faces.

John Andrews is Head of Conservation Planning at the Royal Society for the Protection of Birds, Sandy, Bedfordshire.

### BIOCHEMISTRY OF PARASITIC HELMINTHS JOHN BARRETT

Lecturer in Zoology at the University College of Wales, Aberystwyth.

#### Contents Preface

- 1. Introduction to Parasite Biochemistry
- 2. Biochemical Constituents
  3. Catabolism and Energy Production
- Catabolism and Energy Production
   Nutrition and Biosynthesis
   Metabolic Regulation
   General Summary

7. Appendix Systematic Index Subject Index

Biochemistry of Parasitic Helminths discusses the Biochemistry of Helminths in relation to that of mammals and also in relation to the biochemistry of free-living invertebrates. The book is divided into five sections. The first three parts cover biochemical components (emphasis being given to some of the more unusual compounds which occur in parasites), the pathways of energy production and biosynthetic reactions.

Part four covers, first, the ways in which metabolic pathways are controlled and inter-related. Second, it deals with the metabolic switches which occur during the life cycles of helminths and the ways in which these switches are under environmental and genetic control.

The last section gives a general summary of helminth biochemistry.

The text is intended primarily for use by specialist undergraduate courses in parasitiology and for research workers; it should also appeal to students interested in comparative and invertebrate biochemistry.

A particular strength of the book is the highly structured text which allows easy reference and cross reference and also provides a framework for any reader wishing to access specialist reviews or original papers.

March 1981; £25 hc; £12.95 pb; 318pp hc ISBN 0 333 25668 9; pb ISBN 0 333 25669 7

SCIENTIFIC & MEDICAL

### The Biometry of Plant Growth

#### David R. Causton and Jill C. Venus

This text provides an integrated approach to the quantitative nature of plant growth, combining both biological and mathematical rigour. The authors present the results of original research with an extensive analysis of the form of growth data in relation to the underlying mathematical and statistical properties of the growth analysis methods.

£25 boards 320 pages

### **Ecology for Environmental Sciences**

#### Biosphere, Ecosystems and Man J.M. Anderson

Resource and Environmental Sciences Series
A modern synthesis of ecological concepts
relating to the biosphere and
biogeochemical cycles, natural and
agroecosystems, communities,
populations and man. The effects of man
on his environment, through
populations, pollution and exploitation of
natural resources are emphasized
throughout.

£5.95 paper 208 pages

### Smith's Introduction to Industrial Mycology

Seventh Edition

#### A.H.S. Onions, D. Allsopp and H.O.W. Eggins

The seventh edition has been modified to follow the modern concepts of taxonomy which have resulted from the intensive research of recent years. The chapter on yeasts has been completely rewritten and new chapters on Basidiomycetes and Biodeterioration and its control have been added.

£37.50 boards 408 pages

#### A Biologist's Guide to Principles and Techniques of Practical Biochemistry

Second Edition

### Edited by Bryan L. Williams and Keith Wilson

Contemporary Biology Series

This book aims to make biology students aware of the principles and methodology of those analytical techniques which are fundamental to the development of our understanding of cellular and subcellular processes. The second edition has been revised to include new techniques, in particular a new chapter on immunochemical techniques.

£8.50 paper 336 pages

### Principles and Techniques of Electron Microscopy

### Why should anyone care about extinctions?

Kenneth Mellanby

Extinction: The Causes and Consequences of the Disappearance of Species. By Paul and Anne Ehrlich. Pp.305. ISBN 0-394-51312-6. (Random House, New York: 1981.) \$15.95. To be published in the UK in April 1982 by Gollancz.

PROFESSOR Paul Ehrlich is a distinguished entomologist, known for his meticulous studies of butterfly populations. He is also known to a wider public as a leading prophet of doom. Fortunately, when he has been rash enough to fix dates for particular disasters, his prophecies have seldom been fulfilled. Thus in an article published in 1969 he forecast that "there had been the final gasp of the whaling industry in 1973 . . . by 1977 the annual yield of fish from the sea was down to 30 million tons . . . by September 1979, all important life in the sea was extinct [and] Japan and China were faced with almost instant starvation . . . . ". Now marine pollution has had harmful effects, but the oceans are probably as productive today as they were 12 years ago.

Yet sensible men must agree that our species is increasing in number too rapidly, and that the world's resources are being used too wastefully. The horrors foretold by Ehrlich and others are still possible unless populations are controlled and resources safeguarded. However, I believe

that exaggerated statements of imminent disaster are generally counter-productive. Instead of acting as warnings, they actually induce the complacency they are trying to prevent. They have contributed to what another author has recently described as "a waning of public enthusiasm in America for environmental issues".

In this latest book, Paul and Anne Ehrlich are still concerned with problems of global survival, but they restrict their attention to the way in which man is eliminating many species of plants and animals which coexist with him on the surface of the Earth. They avoid any more rash forecasts of dates when extinctions will occur, and even suggest that we may have 15 or so years to put our house - our globe - in order. They do, however, fear that the rate at which species disappear will accelerate, particularly in the tropics where vast areas of forest are being felled. Few scientists will disagree with their general forecasts of the extinction of species, though their views on the effects on life on Earth are less generally acceptable.

Extinctions have always taken place. There is little doubt that the vast majority of species which have evolved during the 3,000 million or so years during which life has existed on Earth are extinct. Some have suggested that we should therefore not worry about further extinctions; they believe that new organisms suited to

today's world will evolve to fill the vacant niches. Unfortunately this is unlikely, because man produces such sudden changes that there is no time for new forms to evolve. Thus the Ehrlichs point out that much as we may regret, from an aesthetic and scientific standpoint, the passing of the dinosaurs, their place has been taken by mammals and birds. If today we kill off the remaining elephants and rhinoceroses, the world's fauna will be depleted before any replacements have appeared.

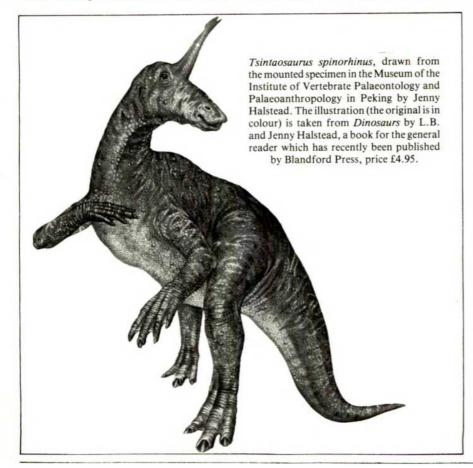

As a conservationist I regret all extinctions, whether locally as of the large blue butterfly in Britain, or globally, as of the dodo, the great auk or the passenger pigeon. I wish I could help to reverse the trend. But we must accept that the majority of people do not care, and in fact are doing much to accelerate the process. How can we convince them of the error of their ways?

The Ehrlichs give four reasons. First, compassion - all species on "Spaceship Earth" have an equal right to exist. Second, aesthetic and spiritual - wildlife contributes to the beauty and interest of the world. Third, economic - many organisms, their potential as yet unrecognized, may be exploited as food or other resources, or may provide essential genetic material for crops, livestock or drugs. Fourth, and in the Ehrlichs' view most importantly, by eliminating other species man is endangering the whole global life-support system, and so rendering our planet increasingly inhospitable to man himself.

What do we mean when we say that all species have an equal right to exist? Logically this would mean that man must do nothing to decrease their numbers or to reduce the area they inhabit. Even those who, for religious reasons, do not kill, farm the land; this can cause local or even general exterminations. If it is the species which has rights, then I suspect that we like to retain some members more for our purposes than for their own.

The Ehrlichs' second reason really boils down to saying that we wish to preserve the species which give us pleasure. This pleasure may have its spiritual or even its religious components, but it acknowledges that we conserve wildlife for man's satisfaction and not for the benefit of the wild creatures themselves.

The statement about the possible economic value of wildlife has some substance. Deer and antelope are proving more efficient converters of some types of vegetation than are cattle or sheep; there may be other animals which will be profitably domesticated. Man has been very conservative in his choice of food crops, and other wild plants may be valuable sources of food. Genes of wild plants may confer valuable properties to existing crop species, so wild grasses and Andean potatoes should be preserved. Unfortunately the species of wildlife for whose preservation most effort is being

made — the large carnivores and herbivores — would seem to have less potential except to provide pleasure and inspiration. But it is obviously good sense to try to preserve large areas of tropical forest and other habitats which contain thousands — perhaps millions — of undescribed species, whose economic potential has not been studied.

Finally, the Ehrlichs believe that unless we can maintain the diversity of the world's flora and fauna, the whole life-support system may break down. This is probably true, but the organisms which are the most important — the decomposers in the soil, insignificant parasitic insects, soil fungi and sewage organisms — are seldom the subjects of popular conservation programmes. The impoverishment of our fauna with the loss of the wolf, the bear and

the wild boar has *not* had the effect of making farming in Britain less efficient — quite the reverse.

So we must come to the conclusion that conservation is a far from simple subject. The economic and similar arguments often need to be qualified. Those based on the value of diversity are far from proven. Conservationists must avoid making statements which they know to be untrue in an attempt to obtain wider support from politicians and the general public. The most cogent reason for conservation, in my opinion, is that "man does not live by bread alone"; the general and aesthetic reasons have more validity than the economic.

Kenneth Mellanby's most recent book is Farming and Wildlife (Collins, 1981).

### Fighting for the conservation of tigers

Brian Bertram

Saving the Tiger. By Guy Mountfort. Pp.123. ISBN US 0-670-61999-X; ISBN UK 0-7181-1991-6. (Viking/Michael Joseph: 1981.) \$16.95, £7.95.

THE tiger is a slim, dramatic animal, and it now has a book to match it. The numerous, large and well-printed colour plates are spectacular and superb. They do not leave a great deal of space for the authoritative text, in which the author summarizes our still scanty information on tigers, their appalling conservation plight and international attempts to prevent their extinction.

Despite the title, the tiger has not been saved, and it would be dangerous to think that it had been. Equally, it would now be much closer to extinction but for international efforts on its behalf. Guy Mountfort was both the catalyst and the power house in setting up Operation Tiger in 1972, under which the World Wildlife Fund raised nearly a million pounds for tiger conservation. He describes how the governments of India, Bangladesh and Nepal were persuaded to establish reserves for tigers, and other countries of Southeast Asia have since followed suit.

The hunting of tigers for sport is no longer a threat, thanks to national legislation in most of the countries concerned. The traffic in tiger skins for the fur trade has dwindled, thanks also to CITES, the Convention on International Trade in Endangered Species. Illegal killing of tigers is declining as local policing improves and as there is less direct contact between tigers and the local populace. The main threat nowadays is from loss of the forest habitat and the prey species on which tigers depend. Through the efforts of Guy Mountfort and others, this threat has been alleviated in many areas, and general

public awareness of the plight of these wonderful animals has been raised.

What about future prospects? First, our priorities. With great difficulty and organization, large sums of money have been raised and thousands of square miles of tiger habitat protected. The total costs involved are equivalent to those needed to build a mere half-dozen miles of motorway. Which is more important? Should we have some form of conservation levy which because we human beings are so numerous would be paltry at the individual level?

Second, the status of tigers in their native reserves is relatively safe only so long as there is no breakdown of law and order in the countries concerned, and until human population pressures become irresistibly strong.

Third, although the many captive tigers in the zoos of the world are not a substitute for wild populations, they may well be a back-up. There should be tigers in the wild where they belong. But if the 350-400 wild Siberian tigers or the 600-800 wild Sumatran tigers are exterminated through human greed or folly, there are at least 800 Siberian and 150 Sumatran tigers in captivity. I am convinced that these could be used to re-stock areas from which wild tigers had been wiped out. Certainly, it would be difficult, and would need money, time and skill, and certainly there would be failures. But there is no reason in principle why, if necessary, reintroduction should not prove possible with tigers as it has with other large cats. We only hope that it does not become necessary. Guy Mountfort has done much more than most to help prevent

Brian Bertram is Curator of Mammals at the Zoological Society of London.

### The sexes look at sex

Adrienne L. Zihlman

The Woman That Never Evolved. By Sarah Blaffer Hrdy. Pp.242. ISBN 0-674-95540-4. (Harvard University Press: 1981.) \$17.50, £12.25. The Evolution of Love. By Sydney L.W. Mellen. Pp.312. ISBN hbk 0-7167-1271-7; ISBN pbk 0-7167-1272-5. (W.H. Freeman: 1981.) Hbk \$15.95, £8.50; pbk \$8.95.

BOOKS on the evolution of human behaviour are often more interesting for the questions raised than for the answers proposed. This is particularly true when one compares the questions posed by male and female authors about the evolution of primate sexuality. The books under review provide a classic case study in contrasting, almost mutually exclusive, viewpoints.

During the 1960s, male reconstructions of human evolution informed us that human hairlessness evolved to enhance front-to-front sex; that men's social and political clubs have sprung from the cooperative cameraderie of the male hunting groups that made our species successful millions of years ago; and that human females lost oestrus and became perpetually sexually receptive so as to keep males around to provide protection and meat from the hunt.

During the 1970s, women increasingly joined men in the game of replaying human prehistory. In place of the prevalent Manthe-Hunter scenario that put males centre stage and relegated passive, dependent females to the wings, waiting for the heroes' return, women anthropologists emphasized the important social and economic role of Woman-the-Gatherer. They also drew on sociobiological theory, which hypothesizes that the sex investing the most time and energy in raising the offspring makes the choice of mates. The central male role in the evolution of human culture and institutions was disputed by field observations on primates and on gatherer-hunters such as the !Kung San, revealing the pre-eminent involvement of females in obtaining and sharing food, choosing mates, socializing children, establishing and maintaining social networks, and using tools - in contrast with the earlier image of females as rather passive recipients of male sexual and hunting activities.

Sydney Mellen's The Evolution of Love and Sarah Hrdy's The Woman That Never Evolved provide examples of the male and female viewpoints of the 1980s. Both are concerned with an evolutionary overview of human nature, particularly sexual nature. Both use the theoretical framework of sociobiology, which attempts to explain contemporary human behaviour by genes that evolved millions of years ago. Mellen draws heavily on the fossil and archaeological record of the past 2–3 million years and does not dwell on non-human

primates, whereas Hrdy goes deeply into the observed behaviour of females of numerous primate species and makes little reference to evolution as read from the fossil record.

According to Mellen, "love" emerged some three million years ago as an important adhesive force for human social groups and for successful child-rearing. His definition of love slides between conscious emotional attachment and sexual attraction; the large human brain is implicitly involved, but how human love differs from the emotional bonds of higher non-human primates is not always clear. His shortest chapter (7 pages) is titled "Love Between Parents and Children", the longest (46 pages), "The Enigma of Homosexual Love", by which he means male homosexual love.

Mellen's book belongs with the 1960s genre in that the framework is Man-the-Hunter and male choice of females. A central issue is male access to females, in order to be assured of their procreative potential, sexual receptiveness and "love" Hunting is credited with our acquisition of intelligence, cooperation, communication and food-sharing (old stuff); and (a new twist) men had many mates and natural selection enhanced "capacities for suspending fear" which resulted in the surviving hunters passing on "their courageous genes ... to many sons". Sociobiological theory tends to find a gene for every behaviour, and so Mellen explains that "finally the world came to be rather full of men whose chromosomes carried certain invidious genes for preferring young women", surely an unnecessary exegesis in a world in which, until very recently, few females or males lived beyond the age of 30 or 40.

The Woman That Never Evolved challenges some of the sexual stereotypes that Mellen perpetuates, almost to the point of reversing them. Hrdy argues that the ubiquitous domination of females by males is a product of primate evolutionary history, as male domination is the rule (with few exceptions) among non-human primates. She brings together a broad array of up-to-date information on females of many species, from galagos to gelada baboons. Of particular interest are the chapters on monogamous primates, among which females enjoy relatively privileged positions, and on those species such as lemurs and squirrel monkeys in which there is no clear dominance of males over females.

Hrdy lays the greatest emphasis on female competition and status-seeking, as though to prove that women have inherited all the same undesirable traits that men possess and therefore should be equally successful. She states that "competition among females is central to primate social organization", and that "every female is essentially a competitive strategizing creature". Obviously, all members of a group "compete" to some extent for food,

status and sexual partners, but, as in an atomic nucleus, the disruptive forces must be less than the cohesive ones if the group is to survive. In most species, male access to females is more limited than female access to males, hence male-male competition would be expected to be, and is observed to be, more intense than competition among females.

Hrdy's evolutionary construct is reminiscent of those of the 1960s, with a sort of reversal of roles. It is females rather than males who are competitive and statusseeking, but instead of forming clubs and political parties, they use their sexuality to gain power and domesticate males and keep them from killing their infants. Hrdy's observation that "outside" male langurs will sometimes take over a troop and kill the offspring of lactating mothers presumably so that they can reimpregnate these females with their own genes — is raised to the level of a paradigm: by the iron laws of sociobiology, primate males will try to "murder" offspring not their own and must be prevented from doing so by female strategems.

The woman that never evolved, according to Hrdy, is the woman invented by contemporary feminists: "created equal", having a natural sense of solidarity with other women and innocent of the male lust for power and status. Hrdy seems to assume that culture plays no role in the behaviour of women, and if certain kinds of behaviour are not found in other primates, they will not be found in humans.

I have improvised a dialogue between Mellen and Hrdy, to contrast their concerns and conclusions. Mellen: "Protohuman females were evolving in the direction of ever-increasing care and nurture of the young". Hrdy: "The vision of assertive, dominance-oriented females differs radically from existing stereotypes of female primates as non-stop mothers whose perennial preoccupation with nurturing offspring keeps them out of politics". Mellen doubts that pleasure from sexual intercourse is common for women. Hrdy retorts that female sexual activity is "assertive and temporarily insatiable".

Both of these books join the growing stacks of sociobiological attempts to integrate genes and human behaviour. They fail by ignoring the intervening levels that influence the outcome of behaviour development, socialization, symbols, ritual and values that are passed on nongenetically from generation to generation. Instead, they invoke hypothetical genes evolved either by hypothetical Pleistocene screenplays or deduced from selected observations on non-human primates and contemporary cultures. Mellen and Hrdy draw nearly opposite conclusions from their gene-based reconstructions. The book that has not yet been written is one that recognizes several levels of analysis, that integrates culture and biology and that interprets female and male behaviour in a mutually adaptive social system.

Adrienne L. Zihlman is a Professor of Anthropology at the University of California, Santa Cruz.

### Taste for travel and a naturalist's eye

A.J. Cain

The Roving Naturalist: Travel Letters of Theodosius Dobzhansky. Edited by Bentley Glass. Pp.327. ISBN 0-87169-139-6. (American Philosophical Society, Philadelphia: 1980.) \$8.

THEODOSIUS Dobzhansky was a truly remarkable man, of great personal experience, shrewdness, humanity and intellectual ability. He wrote clear, vigorous, masculine prose, expressing the forceful thoughts of a first-class observer. This book of his letters and reminiscences is a delight; one can dip into it anywhere and find oneself in grand company. Even when his reactions are the usual ones — to the grandeur of tropical forests, the horrors of temperate-zone poverty or "lousy bureaucracy" - he expresses them with a freshness that always precludes banality. The book would be excellent at one's bedside for those with strength enough to ration themselves to a single letter.

There is an excellent, short biographical

introduction by Bentley Glass which gives the major events in Dobzhansky's extraordinarily varied and interesting lifehistory. He was born in the Ukraine in 1900. In 1910 the family moved to Kiev. The boy, already a keen butterfly collector, went on a school excursion to the Caucasus; two years later he and a friend went off by themselves without parental permission to that fascinating region. His tastes for travel and entomology were already developed.

As a student at Kiev University, supporting his widowed mother, he had a difficult time towards the end of the Great War, and during the Revolution, in 1919, they experienced the Communist terror. Typhus, the invasion of the Polish Army, the death of his mother and severe privations in the winter of 1919–1920 were serious afflictions which he survived, becoming a private tutor, a graduate, an assistant to one of the professors of zoology and a tutor in the Workers'

Faculty, Soon after, he visited Moscow to see the genetical researches of Chetverikov and his group, who had stocks of Drosophila given to them by H.J. Muller. Then he migrated to Leningrad, and was sent on scientific expeditions to Central Asia to study genetic variation in domestic animals — he seems to have studied nearly every other biological phenomenon as well, especially human beings. The first part of this book is his enthralling reminiscences of his travels in Central Asia between 1925 and 1927. In 1927 he and his wife went to the USA to work with Thomas Hunt Morgan at Columbia University, and he began that illustrious career in population

genetics using Drosophila. The problems arising from his investigations into populations of Drosophila in the USA demanded wider genetical explorations. The letters in the book (unfortunately we are never told to whom they were written, which would often clarify their mode of treatment of some topics) were written on his visits to Brazil (1948-1953), to other countries of South America (1955-1958), to Israel, Lebanon and Egypt (1956) and India, Indonesia and New Guinea (1960). He must have been a superb correspondent. As is to be expected, since the reminiscences were taped later in his life and the first letter dates from 1948, his character, after the sometimes hair-raising experiences of his youth, was fully formed. Thus we see no development of character in the book any more than there is in, for example, the short stories of "Saki", but the absence of that is more than compensated for by being able to see through the eyes of so good an observer and writer such a variety of landscapes, organisms, people and situations, sometimes hilarious, often exasperating, but always exciting.

He had a naturalist's eye for animals, plants and people, and excellent appreciation of landscape (less so for geology), a sharpness for human (as well as animal) character, and a lovely dry humour, very like "Saki's", all of which come out just as well in his letters as they did in his conversation. No empty pomposity ever imposed on him, and not many other involuntary psychological deceptions. The freshness of his response to tropical nature seems at first naive (but never boring, gushing or silly) because it is so immediate, but naive he was not. He turned a sharp eye inwards on himself as well - there are some extremely interesting obiter dicta on his own reactions to mountains, uninhabited tropical islands, palms, the tropical night and the Holy

Dedicated drosophilists must be warned that there is little in the book about *Drosophila*. Everyone else will find a lot in it.

### Missing the essential Professor Eysenck

P.E. Bryant

Hans Eysenck: The Man and His Work. By H.B. Gibson. Pp.275. ISBN 0-7206-0566-0. (Peter Owen, London/Humanities Press, New Jersey: 1981.) £11.95, \$26.

THE mainspring of the considerable body of research carried out by Professor Eysenck and his colleagues has always been his theory of personality. This is based on two ideas: the first is that everyone's personality can be described in terms of the person's position along three separate dimensions, and the second that the mechanisms which underlie these dimensions are, in principle, discoverable.

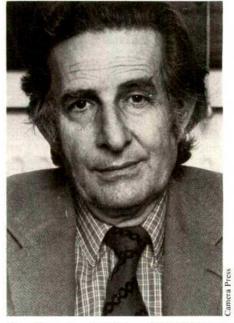

None of the specific details of his account of personality — the use of factor analysis, the three dimensions of introversion—extraversion, neuroticism and psychoticism or the use of the notions of excitation and inhibition and, later, of arousal to explain these dimensions — was in itself particularly new, but it has led to a great deal of original and fruitful research and it has also propelled Eysenck into a series of major controversies.

Anyone who has spent half-an-hour or more with one of his many books will know something of the theory and will also have learned that Eysenck not only revels in these controversies but also writes about them vividly and lucidly. Such characteristics are a distinct advantage in a psychologist. Controversy is the life-blood of psychology. The subject is still finding its feet, and this means that nothing much is certain and nothing can be taken for granted. Every single claim has to be argued over.

No one has recognized this or demonstrated it more than Eysenck. He is nettled, and often quite rightly, by anything that looks like a respectable consensus. It has been the established academic view that individual differences are rather unimportant in psychology, that people with extreme left-wing views are very different in personality from people on the extreme right, that psychoanalysis works, that a person's intellectual abilities are largely determined by the environment in which he grew up, that astrology is bunk and that smoking is a cause of cancer. Eysenck has at various times disagreed quite violently with all these respectable sentiments, and whether or not his objections are right they are always argued

His relish for battle and the clarity with which he presents his blow by blow accounts of them to psychologists and laymen alike represent an important contribution to psychology, but there is much more besides. He, more than anyone, shaped the development of clinical psychology in this country. He, too, fought valiantly and successfully against the unfortunate tendency among psychologists to

break up into quite separate camps which do not talk to each other and which pursue different questions with quite different methods. Eysenck insisted that the question of personality was too important to be left just to the personality testers. The methods of experimental psychology, he argued, were also needed to explain why people are different from each other. He managed to build a bridge between the two camps which has lasted extraordinarily well, so that nowadays no one using personality questionnaires can afford to

Hans Eysenck — "nettled . . . by anything that looks like a respectable consensus".

ignore laboratory research just as no one doing laboratory experiments can resort to the easy assumption that what is true about the behaviour of one person is true as well of everybody else. This link between two hitherto separate disciplines is in my view Eysenck's greatest achievement.

Such a man obviously deserves the accolade of a biography, and H.B. Gibson's account of Eysenck's life coming out as it does near to his retirement ought to give us a good idea not only of Eysenck's own development but also of his considerable influence on psychology over the last three decades. But it does not. Gibson's book is at its strongest when it recounts the simple facts about Eysenck's life - his early upbringing in the Weimar Republic and then under the Nazi regime, his revulsion against the Fascist system and his consequent move to England, his decision faute de mieux to study psychology (mieux in this case being physics), his early work with Burt and then his subsequent move under the tutelage of Aubrey Lewis to the Institute of Psychiatry in order to set up the clinical psychology department there.

But we need to know more than that and

A.J. Cain is Derby Professor of Zoology at the University of Liverpool.

in particular we ought to be told in some detail about the controversies that have taken up so much of Eysenck's academic life, and also about the kind of man he is. On both these counts Gibson's book is a clear failure. He hardly deals with the controversies at all. Eysenck's own views are described reasonably well but the arguments about them, though sometimes mentioned, are never pursued, and again and again Gibson resorts to the excuse that the issues are too complex for his book. This is indeed an unfortunate contrast with the subject of his book who has never hesitated to introduce the layman to exactly the issues which Gibson so consistently avoids.

Thus one of the most obvious opportunities of a book like this — the chance to see how psychology has advanced with the help of lively debates seen through the life of one of its main controversialists - is almost totally lost. Worse still, at times the book's account of Eysenck's controversies is quite seriously misleading. For example, there is a chapter called the "Psychology of Politics" which deals with two very disparate topics. One is Eysenck's theory, published in the 1950s, of the personality types associated with various political views, and in particular his amusing claim that right- and left-wing extremists have much in common, a suggestion which did not endear him either to the left or to the right. The second is the debate about the question of the relative effects of heredity and environment which Eysenck formed so vigorously in the 1970s. As far as I can see, Gibson's only reason for putting these two issues together is his idea that one of the reasons for the violent hostility which greeted Eysenck's views about the importance of heredity was the vindictive rage felt by left-wing elements at the earlier suggestion that they were brothers under the skin of the Fascist foes. There may have been people as lunatic as this, but there were also some serious, well-argued objections which we are not given. We hear about the riots and the punches, but not about the debate.

Nor is the book much more helpful about Evsenck's own personality. It seems that over the years he fell out with many of his important colleagues, but the reasons why remain obscure. Eysenck is apparently shy: yet he has the habit of making outrageously immodest, public claims about his own abilities. Gibson has no explanation for this seeming paradox. Another issue which is left quite unsettled concerns Eysenck's attitude to other people. Gibson takes pains to show how kind Eysenck can be, and often the book adopts the style of a life of one of the saints as it ramblingly recounts this or that good deed by the professor. St Francis gave his cloak to a poor man: Eysenck took a whole day off to fetch a colleague's baby from hospital. But the book also relays some ungenerous comments made by Eysenck about and sometimes directly to other people. I simply do not know what to conclude, and

yet the question is important because one of the major reasons for Eysenck's success has been his ability to keep a large number of people around him working with enthusiasm on his ideas. I should have liked to have known how he did it.

Gibson's book is interesting and often

entertaining. But it gives us nothing like a proper assessment of Eysenck's formidable contribution to psychology over the past three decades.

P.E. Bryant is Watts Professor of Psychology at the University of Oxford.

### Archaeology in retrospect and in prospect

### J. Desmond Clark

A Short History of Archaeology. By Glyn Daniel. Pp.232. ISBN 0-500-05041-4. (Thames and Hudson: 1981.) £9.50, \$17.95. Antiquity and Man: Essays in Honour of Glyn Daniel. Edited by John D. Evans, Barry Cunliffe and Colin Renfrew. Pp.256. ISBN 0-500-05040-6. (Thames and Hudson: 1981.) £25.

It is probably true to say that no school of archaeology has done more in the decades immediately preceding and following the Second World War than has that at the University of Cambridge. There are the unique contributions of Grahame Clark to understanding Mesolithic and Neolithic economy; of Charles McBurney to Palaeolithic studies through his excavations in North Africa, Iran, Afghanistan and Britain; of David Clarke in revolutionizing theory and concepts in archaeology; and of Glyn Daniel through his special interest in and encyclopaedic knowledge of the history of archaeology and the study of megalithic monuments.

These were scholars unsurpassed in their fields and their experience, knowledge and teaching have been responsible for the training of an unrivalled nucleus of the leading archaeologists working in the Western world today. In part this stems from the alliance between archaeology and anthropology that has always been present at Cambridge and the success of archaeological interpretation and model building has come from the understanding of human behaviour provided by ethnographic studies, not infrequently now being undertaken by the archaeologists themselves. While archaeology derives much of its methodology from the natural and earth sciences, interpretation can only come from the insights of the anthropologist. When Professor Glyn Daniel retired this July after 8 years in the Disney Chair at Cambridge and 35 years on the faculty, an era in British archaeology drew to a close. A new group of scholars, often his own students, have taken up the challenge of the modern, conceptual approach to the discipline and are among the leading contributors to it.

There is no one who has made more of an impact than Professor Daniel on our understanding of the history of archaeology and the way that this has influenced current theory, and on the story of its emer-

gence from the enveloping strait-jacket of the Book of Genesis to become the creative and exciting discipline it is today. To celebrate his general editorship and the appearance of the hundredth volume in the Ancient Peoples and Places series published by Thames and Hudson, he has produced A Short History of Archaeology.

The volume is divided into five main chapters that cover the growth of archaeological method and theory from the beginnings, through the formative and then the developmental years between the wars, to that of the "new and not-so-new archaeology". This is a well-written, witty and enjoyable summary of the main conceptual, analytical and methodological advances in the field of prehistoric and historic archaeology as manifested by accounts of the increasing numbers of significant and often very exciting finds, the development of survey, excavation and recording techniques, and the awakening interest of the general public. In other words, it is an excellent history of mankind's ideas about his ancient past. This approach enables archaeologists to appreciate the value of the historical framework that has made possible the advances in field work, analysis and interpretation of the past two decades. By trying to understand the tenor of intellectual thought at a particular time we are better able to appreciate the major developments in archaeological theory and the reasoning that lies behind them.

Following the ordering of assemblages of artefacts in the Three Ages System, to that of the Stage or Age based on stratigraphic excavation and the concept of the "type fossil", archaeology has moved on to determining patterns of economic and social behaviour. The major concern with chronology and time-depth, which for so long occupied the earlier archaeologists, has only been removed since the availability of techniques such as radiocarbon, potassium-argon and the palaeomagnetic reversal chronology made possible by physicists, chemists and geologists since 1950. We are now, therefore, in a position to know, even if we cannot comprehend, the magnitude of the time involved in the story of our biological and cultural evolution.

A Short History of Archaeology is a synthesis not only of the record for

Western Europe but sets out to cover most of the world where archaeologists have made significant contributions. Thus the history of archaeology in the Americas, Africa, the Middle and Far East, and Australasia is discussed, though more satisfactorily for some areas than for others, depending on the author's viewpoint. The dramatic discoveries of Layard, Sohliemann, Petrie, Howard Carter, Arthur Evans and a host of others help to show the way in which archaeology has advanced from an over-emphasis on artefact morphology and typologies to the attempt to learn about the behaviour and the individuals that lie behind the tools themselves. The contributions of the systematic excavators and recorders - Pitt Rivers, Petrie, Mortimer Wheeler - and of those who sought to understand the processes behind culture change like Gordon Childe and the ethnographers receive here the credit they deserve.

Only in the last section of the book on the "new archaeology" does one get the impression that the author is not really in sympathy with his subject. Even though there is not all that much which is new in the more theoretical frameworks and the problem-orientated archaeology of today, it is the emphasis on this problem-orientated approach, coupled with the great advances in technique and method such as "edge polish" studies, spatial analysis, taphonomy and experimental archaeology, that is bringing about such an important re-orientation in our attitudes.

One thing that stands out from Glyn Daniel's intensive search of the literature is the way in which the intellectual world becomes receptive to new hypotheses and new constructs only when it is ready to do so and, although others before may have made the same observations and drawn the same conclusions, unless the scientific world is waiting for them they are quickly forgotten. The manner in which preconceptions can retard true understanding of the evidence is well seen in the early interpretation of Neanderthal man and the ease with which the Piltdown hoax was perpetrated. Glyn Daniel has led the way in showing that archaeology can be of interest for the layman as for the specialist and his works have been the forerunners of those hautes vulgarisations - accounts of all those prehistoric discoveries and palaeoanthropological wranglings - that delight the public today.

An excellent, well-selected set of colour and black and white illustrations accompany the text and this will certainly be a standard introductory textbook for years to come.

Antiquity and Man is not the usual kind of Festschrift which, all too often — as Glyn Daniel himself has said — is "a cemetery of articles which ought to have been published elsewhere in more accessible form, or not at all". The Prince of Wales, who took the archaeology Tripos Part I at Cambridge and was taught by

Glyn Daniel, contributes a foreword, and essays by some 28 leading authorities on archaeological topics and other matters make up the volume. The subjects treated are of direct interest to Glyn Daniel who has had a major involvement with and made a great impact on most of them. It is both a stock-taking of the state of archaeology in the continents today and a discussion of some of the leading theories that lie behind recent advances.

Glyn Daniel, who retired earlier this year after 35 years at Cambridge.

The book is divided into four unequal parts and comprises a valuable series of summary papers on a range of topics which show the extent of Professor Daniel's interest in and contributions to the discipline and also to Cambridge with its college dons and undergraduates. Space does not permit - and it would be invidious to single out - individual contributions from this outstanding text but the first part contains several excellent summaries of the current state of archaeology in Europe and the Middle East, Africa, Australia and China. The reader is made to appreciate the contribution of the Cambridge School to the changing face of archaeology today in Third World countries — the need for the training of nationals to take over from the expatriates and the advantage for both of collaboration and the multidisciplinary, international team approach. Several authors make a plea for fieldwork and warn against its neglect in favour of the theoretical approach which is sometimes only too evident today. Fieldwork is indeed the life blood of archaeology, and models and hypotheses are worthless without the factual empirical data that come from meticulous field methods and objective analysis and interpretation.

Part II comprises nine essays on current theories concerning the construction of megaliths found from the central Mediterranean to Britain and Scandinavia. Glyn Daniel played no small part in elucidating the mystery of their origins and significance. This section will be of especial interest to European archaeologists and shows well the shift in emphasis from the monuments themselves to attempting to learn about the populations that built them and the different economic and social organizations that gave rise to these ritual centres, often associated with communal burial. The diffusionist theory for the spread of megaliths has now been largely replaced by one of local, autochthonous development, while the radiocarbon and TL ages now available show that, far from being derived from the eastern Mediterranean, the megalithic complex preceded in its inception the major monuments of the Ancient Near East.

Part III sets out Glyn Daniel's influence in many different ways in awakening and stimulating public interest in archaeology: as an editor, particularly of the Ancient Peoples and Places series, as an "anchor man" of the television programme Animal, Vegetable, Mineral with Sir Mortimer Wheeler and later of the Buried Treasure series with Paul Johnston. His influence could not have been greater than through his editorship of Antiquity, so ably helped by his wife Ruth as production manager. This is and will remain, it is hoped, one of the leading archaeological journals.

These essays also bring out, especially in Part IV, what is perhaps Professor Daniel's most significant contribution, namely his great success as a teacher. Many of the essays are written by his former students and the high praise and affection with which they all speak of him bears ample witness to the wit and erudition with which he enlivened his lectures and to his natural ability to produce enthusiastic and professional archaeologists who have remained his friends.

Besides being a valuable supplement to A Short History of Archaeology, this volume is full of entertaining asides about archaeology and publishing, amateurs in archaeology and the public image of the archaeologist. It also contains interesting information about Glyn himself, his many achievements and his progresses through the menus gastronomiques of Brittany and the wine country of the Dordogne in his pursuit of archaeology.

Both books show very clearly how the discipline of archaeology is a product of Western European civilization. But the focus has now shifted to the Third World and other countries since it is here that we are learning what it was that made us human. It is here also that archaeology has a greater role to play than in the Western world since, for many nations, it is the most important source of knowledge of their past. Even though this may be regarded as only small beer and lentils, the record is as good as or surpasses that which has gone before

Foreword; Introduction and Acknowledgements; The Stage is Set; The Shadows Before ('Prediscoveries'); Karl Ziegler and the Max Planck Institute; Giulo Natta and the Milan Polytechnic Institute; Fruitful Innovation — 1. The Polyethylene Discovery; Harvesting the Fruits of Innovation — Polyethylene; Fruitful Innovation — 2. Polypropylene; The Falling Out; Harvesting the Fruits of Innovation — Polypropylene; Fruitful Innovation — 3. Synthetic Rubber; The Crest of the Wave — and the Trough; Shadows of the Future; Interpretations; Epilogue; Index.

A narrative account of the remarkable burst of scientific discovery and technological innovations that, beginning in the 1950's, gave science mastery over the 3-dimensional structure of high polymers and has given the world its most useful group of plastics and synthetic rubbers. Emphasis is on the people who made the discoveries and the circumstances surrounding those events.

The initial discoveries in the field of regular high polymers were made by Karl Ziegler in Germany and Giulio Natta in Italy, but many "prediscoveries" can be traced in the ideas and findings of their predecessors. Alhost of scientists and engineers in many different countries expanded and exploited the new field, with important scientific and technological consequences. The key people involved were strong personalities, and their actions, interactions, and controversies provide a multicase study of the conditions and environments that are favourable both to creativity and to the cascade of subsequent developments that convert invention into what may be characterized as "fruitful innovation".

An analysis of the many separate discoveries that highlight this history reveals that the great majority were fortuitous, although they were seldom announced as such. The analysis also shows clearly the critical importance of alert observation and aggressive follow-up. Several additional factors essential to achieving "fruitful innovation" are identified.

### World Climates

### With tables of climatic data and practical suggestions

By WILLY RUDLOFF

1981, 632 pages. Bound DM 180,-

50 figures, 1474 climatic tables, 116 hygrothermal diagrams, 30 other tables and reviews, 1 bicoloured map on the front-papers.

All figures given in the tables represent average monthly and annual values for

#### 1474 locations throughout the world:

- Temperature and extreme values
- Clothing tips for travellers (polar clothing, winter clothing, normal clothing, summer clothing, tropical clothing)
- Stress on the human body caused by heat (with indication of average stress by perspiration)
- Amount of precipitation and number of days with precipitation of 1 mm or more
- Hours of sunshine and percentage of possible sunshine
- Within a division into 16 climatic zones (according to Köppen), the physiological effect of temperature and air humidity on the human body can be seen

Furthermore, the book explains in easily understood language:

- the effect of the global wind systems on the various climatic zones of the Earth (with numerous maps and graphic illustrations)
- adaptation of inhabitants of the Earth to the climatic conditions; reaction of the human body to stress caused by heat and humidity (e. g. cooling requirements in the tropics); indication of clothing conditions
- Köppen's classification of climates

## Superluminal quasar 3C179 with double radio lobes

R. W. Porcas

Max-Planck-Institut für Radioastronomie, Bonn, FRG

VLBI observations of the quasar 3C179 reveal that its two milli arc second components have an apparent relative velocity of 7.6 times the velocity of light. This is the fifth radio source in which 'superluminal' motion has been reported but the first which also exhibits double lobe structure on the arc second scale. Statistical arguments which apply to such sources cause difficulties for explanations based on motion in a relativistic jet.

SUPERLUMINAL motion (apparent relative velocity, v > twice the speed of light, 2c) has been reported for components in the milli arc second radio structure of the strong radio sources 3C345, 3C273, 3C279 and 3C120. The phenomenon has been widely discussed and reviewed<sup>1-7</sup> and some competing, ingenious models have been proposed to explain the illusion 8.9. I report here a fifth example of the phenomenon. VLBI (very long baseline interferometer) observations of the 18 mag quasar 3C179 reveal an expansion rate between its two milli arc second components of 7.6c over the course of 1.2 yr. The source has a higher redshift (z = 0.843, see ref. 10) than the other four superluminal sources and the core is a factor of 10-20 weaker. Unlike the other superluminal sources it has classical doublelobe morphology on an arc second scale. This work was motivated by the suggestion by Scheuer and Readhead11 (repeated by Hine and Scheuer<sup>12</sup>) that such sources should not exhibit superluminal motions.

3C179 (= 0723 + 67) was selected from the quasars mapped by Owen, Porcas and Neff<sup>13</sup> using the NRAO Green Bank interferometer at 2.7 and 8.1 GHz. Thirty of these sources form a set with flux densities at 966 MHz ≥ 0.7 Jy, magnitudes brighter than 19 and angular sizes >10 arc s. Nearly all these quasars have detectable, compact central components. Amongst these, 3C179 has the strongest central component of ~0.5 Jy, contributing ~30% of the flux density at 2.7 GHz, and an outer double-lobed structure with a separation of 14 arc s in position angle (PA) ~80°. At frequencies below ~2 GHz the radio spectrum has a spectral index,  $\alpha$ , of  $-0.75~(S(\nu) \propto \nu^{\alpha})$  but at higher frequencies the spectrum flattens, indicating the presence of the compact component. The radio spectrum, derived from a compilation of published flux density measurements and recent observations, is shown in Fig. 1. The source was not known to be variable in flux density at the time of selection but comparisons of recent measurements at 5 and 10.6 GHz with measurements made in the late 1960s<sup>14,15</sup> suggest that the core is variable, both on a 10-yr and a 1-yr time scale.

#### **Observations**

VLBI observations were made of 3C179 at two epochs, 1-2 October 1979 and 9 December 1980, at a frequency of 10.7 GHz. The telescopes at Effelsberg (FRG), Haystack (Massachusetts, USA), Green Bank (West Virginia, USA) and Owens Valley (California, USA) were used, and the hydrogen maser frequency standards used at all the sites permitted coherent integration times of 4 min. The Mark 2 VLBI recording system used for these observations achieved an r.m.s. error per point of 12-20 mJy on the high resolution transatlantic baselines. The interferometer lobe spacing on the longest baseline is  $\sim 0.5$  m arc s. In both observing sessions at least 11 h of good data were obtained at all the telescopes. The data were processed using the Max-Planck-Institute VLBI processor in Bonn and the visibility functions were calibrated using

measurements of the individual antenna gains and system temperatures.

#### Results

The most interesting structure in 3C179 is revealed by the high resolution transatlantic baselines. In Fig. 2a, c, e, the visibility functions measured on these baselines in October 1979 are plotted. These clearly show the oscillatory nature characteristic of a double morphology. Simple gaussian modelling of the sky brightness distribution gives an excellent fit to the visibilities with two components, of flux ratio ~2:1, separated by 1.07 m arc s in PA  $92^{\circ}$ . This orientation is within  $\sim 12^{\circ}$  of the PA of the outer structure although the latter is not well defined as both outer components are heavily resolved13. This may be compared with the good alignment of inner to outer structure generally observed in the central components of double-lobed sources such as Cygnus A, 3C111, 3C390.3, NGC6251 and 3C236 (refs 16-19). However, this is the first time that the structure of the central component of a double source identified with a quasar has been determined. Those quasars which have been observed to date have asymmetric outer structure and generally show marked bending between the angles of the inner and outer structure (for example, 3C380, 3C147 and the superluminal sources 3C345, 3C273 (ref. 19)).

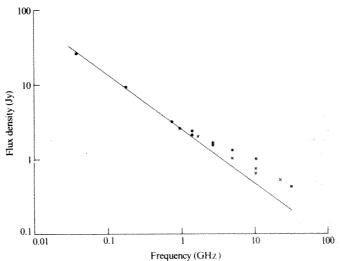

Fig. 1 The radio spectrum of 3C179. Reference numbers for measured flux densities at different frequencies are shown in parentheses. UE, unpublished measurements made with Effelsberg 100-m telescope between 1979 and 1981, marked with crosses. 38 MHz (35); 178 MHz (36); 750 MHz (37); 966 MHz (10); 1.4 GHz (37, 38); 1.7 GHz (UE); 2.7 GHz (13, 39); 5.0 GHz (14, UE); 10.7 GHz (15, UE); 22.7 GHz (UE); 31.4 GHz (40). The straight line through the low frequency points represents a spectral index of -0.75.

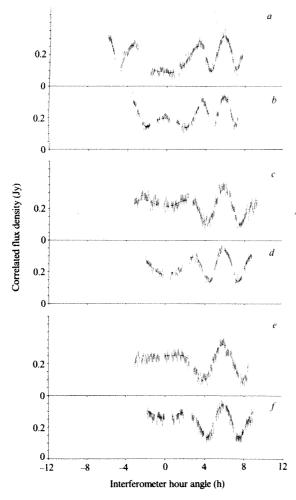

Fig. 2 Correlated flux density of 3C179 on various baselines versus interferometer hour angle. The solid line represents the best two-component fit. Baselines: a, b, Effelsberg-Owens Valley; c, d Effelsberg-Green Bank; e, f, Effelsberg-Haystack. a, c, e were measured in October 1979; b, d, f were measured in December 1980.

The visibility functions for the same baselines observed in December 1980 are shown in Fig. 2b, d, f. Again the structure is clearly double, although it is equally apparent that structural changes have occurred. The most interesting feature is the narrowing of the distance between the peaks and troughs of the visibility function, corresponding to a larger separation of the two components at the later epoch. Gaussian model fitting confirms this, giving a separation of 1.24 m arc s in the same position angle. The results of the gaussian parameter fits to the data from both epochs are given in Table 1, along with the single dish flux densities for the whole source measured in Effelsberg. With the standard values of the cosmological parameters used in previous studies of superluminal sources  $(H_0 = 55 \text{ km s}^{-1} \text{ Mpc}^{-1}, q_0 = 0.05) 3C179 \text{ has an apparent separation}$ velocity between components of  $7.6c \pm 1c$ . This makes it the fifth known source exhibiting superluminal motion between milli arc second components. Projecting back the separation rate gives the epoch of zero separation as ~1972.0; unfortunately, no flux density monitoring of 3C179, which would indicate any outbursts, seems to be available for this time.

An additional change that has occurred during the 1.2 yr between the two observing epochs is the depth of the minima in the visibility functions, which have become shallower with time, indicating that the flux densities of the two components have become more unequal. This is very similar to the behaviour of the superluminal source 3C345 reported by Cohen et al.<sup>20</sup>; however, in the case of 3C179, the model parameters and total flux densities given in Table 1 indicate that the stronger component has increased, whereas in 3C345 it is the weaker component which decreases or perhaps becomes more diffuse and complex<sup>20,21</sup>.

At both epochs the individual components each seem to be resolved and it is unclear from the models which of the components could be identified with the core and the jet usually mentioned in the context of radio source milli arc second structure. There are strong indications from the closure phase, however, that the stronger (east) component is more compact than the weaker (west) component, and thus corresponds to the core.

Pearson et al.<sup>7</sup>'s hybrid maps of the strong source 3C273 clearly demonstrate the superluminal motion of one of its components. Although this technique is unsuitable for the present observations of 3C179 because of the relatively poor sensitivity on many of the inter-American baselines, the following checks indicate that the gaussian model well represents the real source structure:

- (1) The r.m.s. residuals from the model fit are in close agreement with those expected due to random noise and small  $(\sim 3\%)$  calibration uncertainties.
- (2) Attempts to force a fit at either epoch with the mean angular separation of 1.16 m arc s, and allowing component sizes and fluxes to change, fail to produce a good fit to the data.
- sizes and fluxes to change, fail to produce a good fit to the data.
  (3) The closure phase<sup>22</sup>, where it exists, is in excellent agreement with that predicted from the models.
- (4) Separately model fitting the individual baselines independently gives the separations quoted in Table 1 at each epoch.

#### Discussion

It is interesting to compare the observed behaviour of 3C179 with the various models previously proposed to account for the phenomenon. However, many of the observational tests for distinguishing between models require more than two observing epochs. For 3C179 the two epochs indicate a superluminal expansion rather than contraction and it is the fifth source where this is true. (Random brightening of stationary components, as proposed by Dent<sup>23</sup>, would predict an equal number of contractions). The magnetic dipole model<sup>24</sup> requires a separation velocity >4.4c; on the basis of the cosmological parameters adopted, this condition is satisfied by the present observations.

Two further explanations of the superluminal effect require intrinsically improbable circumstances which, however, are preferentially selected when compact sources with strong radio emission are observed. In the gravitational lens model<sup>25</sup> a foreground galaxy magnifies a subluminal motion in the quasar; angular magnification makes the motion superluminal and flux density magnification makes the source bright. The compact core in 3C179 is much weaker than those of the previously known superluminal sources and thus the preferential selection

			Table 1	Model parameters				نه ،
Epoch	Single dish flux (mJy)	Component	Flux (mJy)	Separation (m arc s)	PA (deg)	Major axis size (m arc s)	Minor axis Major axis	PA (deg)
October 1979	$670 \pm 15$	W E	$114 \pm 5$ $209 \pm 8$	- 1.07 ± 0.01	92±1	$0.34 \pm 0.05$ $0.24 \pm 0.05$	$0.2 \pm 0.1$ $0.0 \pm 0.1$	$95 \pm 5 \\ 88 \pm 5$
December 1980	$720 \pm 15$	W E	$107 \pm 5$ $240 \pm 8$	$1.24 \pm 0.01$	92±1	$0.32 \pm 0.05$ $0.18 \pm 0.05$	$0.3 \pm 0.1$ $0.0 \pm 0.1$	82±5 78±5

cannot be operating so strongly, unless central components of double-lobed sources are intrinsically weaker.

The most widely discussed explanation involves relativistic motion of the radio emitting regions in the superluminal sources. In the relativistic jet model, for example 11.26, the superluminal effect arises from the time delay between the two components when the angle,  $\theta$ , of the motion to the line of sight is small. The relativistic motion towards the observer has the additional effect of enhancing the measured flux density by relativistic Doppler boosting (see ref. 27). This model has two essential elements: the Lorentz factor,  $\gamma$ , of the relativistic motion must be  $\geq$  the apparent velocity/c and for the minimum value of  $\gamma$  (in this case  $\gamma = 7.6$ ) the angle,  $\theta$ , to the line of sight must be  $\sim 1/\gamma$  ( $\theta \approx 7.5^{\circ}$ ).

As there seems to be good alignment between the position angle of the structure of central components and that of the outer lobes, one might assume that the entire source axis is inclined at this small angle, making the true, deprojected angular size  $\sim 107$  arc s. This is rather large for a quasar at this redshift (see ref. 28) and corresponds to a linear size of ~1 Mpc; this is not, however, compelling evidence against such a small angle.

A more serious objection arises from the enhancement of flux density associated with high  $\gamma$  and small  $\theta$ . 3C179 was chosen from a sample of 30 quasars with large (≥10 arcs) structure. Although the selection of 3C179 from the sample is biased towards a high  $\gamma$  and small  $\theta$ , the sample of 30 sources is not biased towards small  $\theta$ , because the outer lobe flux densities, which dominate in these sources, have been shown to be 'unbeamed'<sup>29,30</sup>. Thus it is unlikely, a priori, that a source with the required small angle  $(P \sim 0.009)$  exists in the sample with the

required value of  $\gamma$  unless  $\gamma \sim 7.6$  is typical for the sample. (This argument is independent of any alignment of inner and outer structures). Scheuer and Readhead's prediction of a lack of super uninal motion in such sources is based on their assertion that the typical  $\gamma$  can be no more than  $\sim$ 2 in such double sources because the observed range of boosting factors in central components is low. If this argument is correct, 3C179 must be regarded as a freak within the sample, with  $\gamma$  and  $\theta$  conveniently contrived for the observation of the superluminal

Because relativistic motion has been used to explain the rapid flux density variations in compact sources<sup>31</sup>, and relativistic jets ecount for the efficient transfer of energy from the nucleus to the outer lobes (see ref. 32) and other morphological aspects of radio sources<sup>33,34</sup>, there are reasons for retaining the idea of relativistic motions in compact radio sources. One way to ease the problem is to adopt a rather higher value of the Hubble constant. With  $H_0 = 100$  the required  $\gamma$  becomes  $\sim 4.2$ ,  $\theta \sim 14^\circ$ and overall size ~300 kpc for 3C179. However, the detection of superluminal motion in the first source of the type predicted not to how it suggests that the effect may be very much more common than at present thought.

### Non-tandem arrangement and divergent transcription of chicken histone genes

R. P. Harvey, P. A. Krieg, A. J. Robins, L. S. Coles & J. R. E. Wells Department of Biochemistry, The University of Adelaide, North Terrace, Adelaide, South Australia 5001

We have located chicken histone genes within 14-kilobase pd inserts of two genomal clones, λCH-01 and λCH-02. The genes were mapped with chicken histone cDNA and gene-pecific probes, and the identity and polarity of each gene confirmed by DNA sequencing. As previously indicated, histolee mRNAs are transcribed from both DNA strands. The gene organization differs in the two clones. Although there is some clustering of genes, no repeating unit is observed. λCH-01 contains all core histone genes, but two copies of H2A occul before the full complement of histone genes is represented. λCH-02 contains no H4 or H2A genes, but notably has two adjacent H3 genes which are divergently transcribed. H2A, H2B and H3 genes all appear more than once in the combiled inserts of the two clones, but in no case do they occur in equivalent environments. This indicates a considerable degite of disorder of the histone genes in the chicken genome.

HISTONES comprise a small group of basic proteins whose primary function is in forming the structural matrix of nucleosomes (for review see ref. 1). The amino acid sequences of histones exhibit only a narrow spectrum of divergence through

evolutionary time, consistent with their structural role in the ubiquitous nucleosome particle. In addition, species- and tissuespecific histone subtypes have been widely observed and these are regulated during embyrogenesis and spermatogenesis

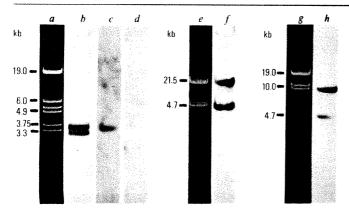

Fig. 1 Hybridization of 'histone' cDNA and specific gene probes to λCH-01 and λCH-02. Restriction digests of λCH-01 and λCH-02 DNA were electrophoresed in 1% agarose slab gels and the DNA transferred to nitrocellulose sheets<sup>28,29</sup>. The filters in tracks c, d, e and f were hybridized with <sup>32</sup>P-DNA probes labelled by nick translation<sup>30,32</sup>P-cDNA (tracks b, h) was reverse-transcribed from 5-day embryo 7-11S RNA<sup>17</sup>, using the random priming method<sup>31</sup>. The sea urchin H3 and H4 probes were constructed from fragments of the sea urchin H3 and H4 probes were constructed from fragments of the sea urchin H3 and H4 probes were constructed from fragments of the sea urchin H3 and Fagment of the H2B gene, track d shows that this does not hybridize to the chicken H2B gene. The chicken H2A probe was the Xhol-Xhol fragment of pCH3.3E (see Fig. 2a, fragment D), resolved on polyacrylamide slab gels and eluted as for DNA sequencing<sup>33</sup>. a, A Hind3-EcoRI digest of λCH-01 viewed by UV illumination of an ethidium bromide-stained gel. Sizes were determined by reference to Hind3-digested λ DNA run in the same gel. b, c, d, Hybridization to this λCH-01 digest with histone cDNA, sea urchin H4 probe and sea urchin H3 probe, respectively. e, A Sma-Hind3 digest of λCH-01. f, Hybridization to this digest with the chicken H2A probe. g, An EcoRI digest of λCH-02 visualized ethidium bromide-stained fragments. h, Hybridization of this digest with histone cDNA.

(reviewed in ref. 2). The amino acid changes which specify each subtype often occur in the otherwise conserved globular domains. These changes, and a variety of post-synthetic modifications<sup>2,3</sup>, may alter nucleosome structure and function. It has been suggested that subtype switching is intimately related to chromatin remodelling during development of new cell types<sup>4,5</sup>. The interaction of histones with both cell cycle and developmental events implies that their expressional requirements may be complex. Superimposed on this, the structure of the nucleosome dictates the need for strictly equimolar amounts of 'core' histones, and approximately half molar amounts of the

H1 group<sup>6</sup>. These requirements have provoked much interest in the structure and evolution of histone genes.

The highly reiterated 'early' histone genes from several species of sea urchin have been extensively characterized (for review see ref. 7). A repeating unit containing one each of the five histone genes is reiterated in tandem along the chromosome. Some histone variants are encoded in the DNA of less frequent repeats<sup>8</sup>. Selective expression of different repeat units has been observed, accounting for the appearance of variant histone proteins at specific stages of sea urchin development<sup>9,10</sup>. It has been recently shown that individual histone gene 'orphons' are also present in sea urchin DNA<sup>11</sup>.

The histone genes of *Drosophila* are organized into a compact repeat unit containing all five genes<sup>12</sup>, but both gene order and relative gene polarity differ from the sea urchin arrangement. In *Xenopus*, histone genes are clustered and tandem arrangement is observed<sup>13,14</sup>. Nevertheless, preliminary examination of two clones shows that gene order may vary<sup>13,14</sup>. In yeast<sup>15</sup> the genes for the H2A and H2B proteins are linked and transcribed in a divergent fashion. They are represented only twice in the yeast haploid genome and the two H2A/H2B pairs are spatially distinct from one another and also from the H3 and H4 histone genes.

We have previously reported the isolation of a genomic chicken histone clone,  $\lambda \text{CH-}01^{16}$ . Here, we locate and orient core histone genes in this clone and extend the analysis to a non-overlapping clone  $\lambda \text{CH-}02$ . There is no indication of tandemly repeated genes in these inserts, and the data indicate a lack of order of chicken histone genes.

#### Coding potential of $\lambda$ CH-01 and $\lambda$ CH-02

Coding regions were located in each unit by hybridization of restriction digests of the whole clone with 'histone' cDNA, and all cDNA-positive regions were subsequently shown to contain core histone-coding regions by DNA sequence analysis. Although the embryonic RNA from which the cDNA was transcribed translates into the five histone proteins in the wheatgerm cell-free system<sup>17</sup>, it is possible that embryonic cDNA does not detect tissue-specific H1 gene variants<sup>13</sup>.

Two major coding regions were identified within a Hind3-EcoRI digest of  $\lambda CH-01$  (Fig. 1a, b and ref. 16). These two fragments of 3.3 and 3.75 kilobase pairs (kbp) were ligated into the plasmid vector pBR325 to generate the subclones pCH3.3E

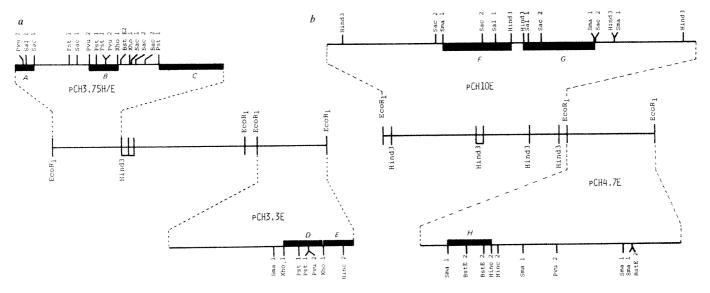

Fig. 2 Restriction endonuclease maps of λCH-01, λCH-02 and subclones derived from them. Blocked-in regions indicate fragments which hybridized with histone cDNA. Combinations of restriction enzyme digests were used to compile the data from the plasmid subclones and only those sites are shown which were of practical use in precise location and subsequent DNA sequence analysis of individual genes (see Figs 3-5). The insert size of λCH-01 is 14 kbp and that of λCH-02 14.7 kbp. All maps of the subclones except pCH10E have been enlarged three times relative to the overall λCH-01 or λCH-02 maps. The size of pCH10E has doubled relative to λCH-02. The position of the small EcoRI fragment of λCH-01 is corrected here from its previous allocation 16. a, cDNA-positive regions A, B, C, D, E of λCH-01 subclones pCH3.75H/E and pCH3.3E, respectively. b, cDNA-positive regions F, G, H of λCH-02 subclones pCH10E and pCH4.7E, respectively. These regions are referred to in the text and are subsequently identified by DNA sequence analysis (Figs 3, 4).

and pCH3.75H/E, respectively. The subclones were mapped with restriction endonucleases and coding regions were located in finer detail using histone cDNA (Fig. 2a). Five coding regions (A-E) were identified, suggesting that  $\lambda$ CH-01 encoded multiple genes.

A similar analysis of  $\lambda$ CH-02 revealed coding regions within both the 10- and 4.7-kbp EcoRI fragments (Fig. 1g, h). These were subcloned (pCH10E and pCH4.7E) and further mapping and cDNA hybridization studies revealed three coding regions, F-H (Fig. 2b).

### Detection of genes in CH-01 using specific coding probes

To identify the coding regions indicated in Fig. 2a, we screened  $\lambda$ CH-01 with specific gene probes. Due to the conservation of histone amino acid sequences through evolution, sea urchin probes have proved useful for detecting histone genes of other species<sup>12</sup>. Our own findings suggest, however, that these cross-species probes must be used with caution. Although the H4 sea urchin probe showed specific hybridization to chicken recombinants, the sea urchin H3 probe and a probe containing a fragment of the *Drosophila* H2B gene gave ambiguous hybridization results when used on  $\lambda$ CH-01. Similarly, results from this laboratory indicate that the sea urchin H3 gene probe does not cross-hybridize unambiguously with an authentic human H3 histone gene. These observations question the results of previous attempts to detect histone gene transcripts in mammalian cells<sup>18,19</sup> using sea urchin probes.

The presence of an H2A gene in  $\lambda$ CH-01 has been previously recognized from DNA sequencing <sup>16</sup>. This was unambiguously located in pCH3.3E (Fig. 2a, region D) from the position of restriction sites. An H2A gene-containing fragment bounded by XhoI sites (Fig. 2a, region D) was excised and used as probe to re-screen  $\lambda$ CH-01. The sea urchin H4 probe and the homologous H2A probe hybridized to  $\lambda$ CH-01 (Fig. 1c and f, respectively). No hybridization was observed with the sea urchin H3 probe (Fig. 1d). The H2A probe hybridized to two distinct regions (Fig. 1f), indicating the possibility that  $\lambda$ CH-01 contained two H2A genes.

### H3 and H2B genes identified in cDNA-positive regions of $\lambda$ CH-01 and $\lambda$ CH-02

As noted above, H3 and H2B heterologous probes were unsatisfactory for detailed analysis of the chicken histone clone  $\lambda$ CH-01. Fine hybridization mapping of the subclones pCH3.75H/E and pCH3.3E indicated two cDNA-positive regions, A and E (Fig. 2a), that did not hybridize with the available cross-species probes. Direct DNA sequence analysis identified these regions as H3 and H2B genes, respectively (Fig. 3).

The genomic clone  $\lambda$ CH-02 was originally identified as a histone gene clone on the basis of hybridization with a histone cDNA probe (ref. 1 and Fig. 2b). It did not hybridize with heterologous H2B or H4 probes (data not shown); however, the cDNA-positive regions F, G and H (Fig. 2b) did hybridize with H3 and H2B coding regions derived from  $\lambda$ CH-01. DNA sequence analysis of these regions showed that regions F and G of  $\lambda$ CH-02 contain adjacent H3 genes and that region H contains an H2B gene.

Thus, all cDNA-positive regions of  $\lambda$ CH-01 and  $\lambda$ CH-02 were shown to contain chicken histone genes. Portions of the nucleotide sequences which serve to identify each of these genes are shown in Fig. 3.

#### Location and orientation of histone genes

The precise location and orientation of all the core histone genes in  $\lambda CH$ -01 and  $\lambda CH$ -02 may be deduced from restriction enzyme mapping and DNA sequence analysis (Figs 2, 4). All core histone coding regions present in  $\lambda CH$ -01, except for one region in an H2A gene, have been fully sequenced (Fig. 4). In each case the nucleotide sequence predicts the expected amino

Fig. 3 Identification of histone genes in λCH-01 and λCH-02 by DNA sequence analysis. DNA sequences of all genes except the H2B gene in pCH4.7E were determined by the methods of Maxam and Gilbert<sup>33</sup>. Sequences from this gene were obtained by the methods of Sanger and Coulson<sup>34</sup>. The nucleotide sequences shown cover a region coding for the first 10 amino acids of each protein. The amino acid sequence for chicken H4 and H2B are not known. The genes for these proteins were assigned by comparing the amino acid sequences predicted in one reading frame with the respective calf amino acid sequences. The identifying DNA sequences are given in the order A to E and F to H shown as cDNA-positive regions of λCH-01 and λCH-02, respectively, in Fig. 2a and b. The extent to which nucleotide sequences have been determined in each coding region is shown in Fig. 4.

acid sequence for the respective histone protein. There are no intervening sequences or frameshift mutations and thus the genes located within  $\lambda CH$ -01 are not pseudogenes. The limited nucleotide sequence data for the H3 and H2B coding regions in  $\lambda CH$ -02 so far predict amino acid sequences expected for these two histones. The notable feature of  $\lambda CH$ -02 is the presence of adjacent, divergently transcribed H3 genes, separated by about 0.8 kbp of DNA. Although the H2A/H2B and H3/H4 gene pairs of yeast<sup>15</sup> and Drosophila<sup>12</sup> are divergently transcribed, this kind of organization for a histone gene pair coding for the same protein has not been described previously. The significance of the H3 gene pair disposition in the chicken system is unclear. By extrapolation from the recently described chorion gene system<sup>20</sup>, it is possible that the organization of divergently transcribed genes is significant for the expression of tissue-specific variants.

The overall arrangement of core histone genes within λCH-01 and  $\lambda$ CH-02 is shown in Fig. 5a and b, respectively. The two nserts are non-overlapping and although some clustering of genes occurs, there is no obvious tandem repeating unit. Within λCH-01, the H2A gene appears twice before a full complement of core histone genes is represented. The tightly linked H2A/H2B gene pair seen in λCH-01 is not present in λCH-02 and the adjacent H3 genes in ACH-02 are not related in an organizational sense to the H3 gene in  $\lambda$ CH-01. In other words, no two genes coding for the same histone are in equivalent environments. (These results refute our previous indication of a 15-kbp repeat for chicken histone genes using uncloned probes<sup>17</sup> and are consistent with preliminary analyses of other and are consistent with preliminary analyses of other chicken histone clones<sup>21</sup>.) The clones also contain long stretches of non-histone DNA. For example, in ACH-01, 9 kbp of DNA separate the H4 gene from the distal H2A gene (Fig. 5a) and an inter-gene distance of 4 kbp is seen in  $\lambda$ CH-02 (Fig. 5b).

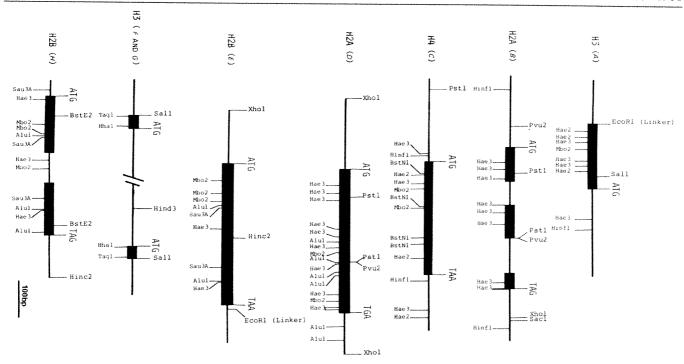

Fig. 4 The coding regions of genes in λCH-01 and λCH-02. Initiation and termination codon sites are shown for each gene where known. Restriction sites above the line can be used to orient the genes (see also Fig. 2). The blocked areas indicate coding regions for which the nucleotide sequence has been determined. Each gene fragment is identified A to H relative to the cDNA coding regions indicated in Fig. 2.

The relative disorder of histone genes in chicken may contribute to an understanding of histone gene evolution. The histones themselves represent highly conserved proteins with a defined function and it is unlikely that the mode of expression of histone genes would have changed dramatically through evolution. Preliminary data on a human histone gene clone (ref. 22 and unpublished data) suggest that marked histone gene disorder may also occur in other vertebrates. Although histone genes are frequently organized into ordered repeating units, there is little to suggest that this is a requirement for expression. The relative disorder of chicken histone genes also suggests that they are independently controlled. An explanation is therefore required to account for the evolution of histone genes from an ordered to a disordered disposition. It is possible that the concerted evolution of histone gene clusters in invertebrates is a function of chromosomal correction mechanisms acting on reiterated genes<sup>23-27</sup>, and that non-concerted evolution of chicken histone genes has arisen because the vertebrate gene copy

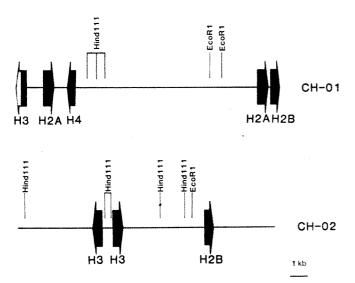

Fig. 5 Location and orientation of chicken histone genes. The precise location and orientation of genes in the two clones  $\lambda CH$ -01 and  $\lambda CH$ -02 relative to EcoRI and Hind3 restriction sites are indicated.

number is low<sup>7</sup> and correctional recombination events are less frequent. In this view, the gene organization in chickens is a remnant of the ordered arrangement of invertebrates, conserved in these species because they are more highly reiterated and not because of a functional requirement.

Clustering of histone genes in tandem arrays as first described for invertebrate systems remains the predominant histone gene organization in those species studied so far. Variations are seen in sea urchin orphons<sup>11</sup>, yeast<sup>15</sup> and Xenopus<sup>13,14</sup>. More recent data confirm that the major histone gene unit in *Xenopus* is a 14-kbp clustered array<sup>13,14</sup> and that the variants  $\lambda$ Xlh4 (ref. 13) and Xl-hi-1 (ref. 14) may be 'orphon like'. Unequal recombination events could result in the appearance of isolated genes or groups of genes, and these elements might be expected to show extensive population polymorphism as is indeed the case for sea urchin histone gene orphons<sup>11</sup> and the minor histone gene components of *Xenopus*<sup>14</sup>. It is unlikely that the chicken histone genes analysed here represent orphons. Southern blot analysis (ref. 21 and our unpublished data) is not consistent with the existence of a major repeating histone gene cluster in the chicken genome.

We thank Drs E. Jacob and C. Parker for sea urchin and Drosophila histone gene probes, respectively. This work was supported by ARGC grant D276/15788 to J.R.E.W.

### Sequence homologies near the C-termini of the variable surface glycoproteins of Trypanosoma brucei

Allison C. Rice-Ficht, Kenneth K. Chen & John E. Donelson

Department of Biochemistry, University of Jowa, Iowa City, Iowa 52242, USA

African trypanosomes evade their mammalian host's immune system by the sequential expression of alternative surface glycoproteins. Comparison of the cDNA sequences of five antigenically distinct surface proteins and the C-terminal amino acid sequences of four additional ones demonstrates that these nine glycoproteins can be classified into two subsets based on C-terminal amino acid homologies that extend 75-105 amino acids into the protein.

UNICELLULAR parasites of the genus Trypanosoma cause extensive disease in both humans and livestock1. In Africa the disease is especially widespread among domestic livestock and thus severely limits the consumption of meat and milk products by over 200 million people living south of the Sahara Desert2. The parasite resides in the bloodstream of its mammalian host and appears to evade the host's immune response by sequentially expressing a series of different surface glycoproteins, the variable surface glycoproteins (VSGs)<sup>3,4</sup>. The largest documented number of immunologically distinct VSGs that can arise from a single trypanosome clone is 101, reported for Trypanosoma equiperdum<sup>5</sup>; the maximum potential number is unknown

VSGs isolated from Trypanosoma brucei are best characterized. The VSGs constitute at least 95% of the surface protein of this organism and as much as 10% of the total cell proteins<sup>6</sup>. T. brucei VSGs have molecular weights between 55,000 and 65,000 and most of those studied have widely different amino acid compositions, dissimilar peptide maps, different isoelectric points and variable carbohydrate content<sup>7-11</sup>. In addition, the N-terminal sequences of 15-30 amino acids reported for five different VSGs are very different and have no obvious relationship<sup>3,9</sup>. Nevertheless the different VSGs do have a similar biological function. They comprise a cloud or shell that shields other membrane proteins from the host's immune system. As such, each collection of unique VSGs must be able to assume a uniform and closely ordered array on the surface of the organism.

Here we compare five different VSG cDNA sequences and, together with the C-terminal amino acid sequences of four others, demonstrate that the VSGs characterized so far can be grouped into two major subsets based on amino acid homologies near the C-terminus.

#### Origin of the VSG cDNAs

The ILTAT series of T. brucei clones are derived from LUMP 227<sup>12</sup>, which originated from a trypanosome stock isolated in 1964 from a cow in Kenya<sup>13</sup>. They are serially related as follows.

LUMP 227 
$$\rightarrow$$
  $\rightarrow$  ILTAT 1.1  $\rightarrow$  ILTAT 1.2

ILTAT 1.4

In each case the ILTAT clone was isolated from the first

teppanosome relapse population in an experimental animal infected with the previous clone: for example, ILTATs 1.3 and 14 were each isolated from a laboratory mouse infected with ILTAT 1.2. The construction, identification and initial characterization of the four ILTAT VSG cDNAs are described elsewhere 14-1

The partial sequence of VSG 117 cDNA, shown in Fig. 1, was recently reported by Boothroyd et al. 18. Trypanosome clone 117 is derived from another T. brucei stock isolated in 1960 from a sheep in Uganda19.

#### VSG nucleotide coding sequence homologies

Sucleotide sequences of VSG cDNAs of ILTAT 1.2, ILTAT 1.3 and 117 are compared in Fig. 1; the sequences of ILTAT 1.1 and 1.4 cDNAs are compared in Fig. 2. No direct amino acid sequence information is available on the ILTAT VSGs. However, the amino acid sequences of each can be deduced from the nucleotide sequences as each contains only one large translation reading frame uninterrupted by termination codons. The largest cDNA, ILTAT 1.3, extends 1,515 nucleotides from the 5' end of the cDNA to the (DNA) termination codon TAA, followed by 87 nucleotides (including three additional termination codons in phase) before the poly(A) region is reached. The corresponding protein of 505 amino acids has a molecular weight (MW) of 54,886, which is within the range of native VSGs, if adjusted for the addition of carbohydrate moieties and the potential proteolytic processing of an N-terminal signal sequence<sup>20</sup> and the hydrophobic portion of the C-terminus<sup>18</sup> Unfortunately there is no definitive way to determine from the nucleotide sequence alone whether one of the two methionine odons near the start of the ILTAT 1.3 coding sequence is the ranslation initiation codon. The 16 hydrophobic amino acids hat immediately follow the second of these methionine residues ossibly represents an N-terminal signal peptide although there s no experimental evidence for this conclusion. The other DNAs are smaller and do not contain the entire VSG coding

Comparison of the nucleotide sequences in Figs 1 and 2 eveals striking homologies among VSG coding sequences preiously thought to be unrelated based on nucleic acid hybridizaion studies<sup>21</sup>, N-terminal amino acid analyses<sup>3</sup>, and antibody ross-reactivity<sup>6,12</sup>. In Fig. 1, the sequences of ILTAT 1.3 and 17 cDNAs were initially compared by aligning the termination odons of their open translation reading frames. The ILTAT 1.2

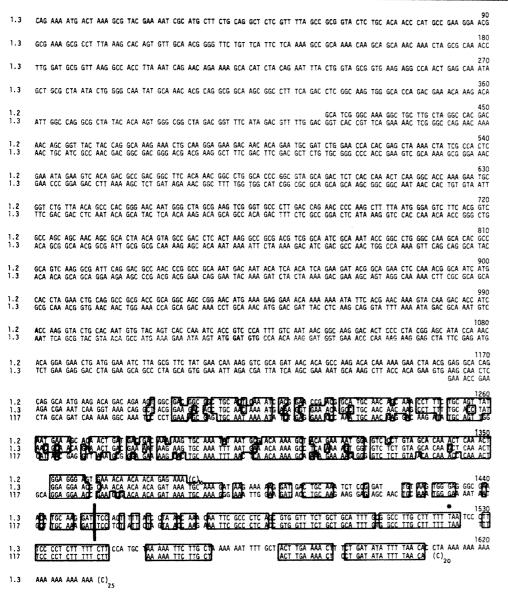

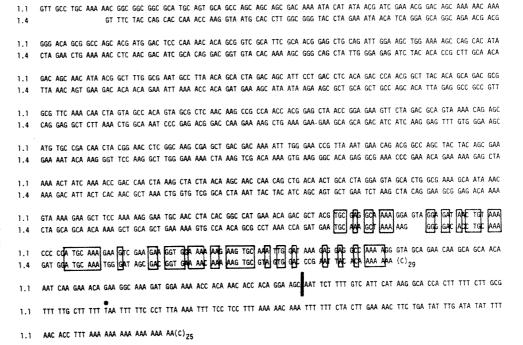

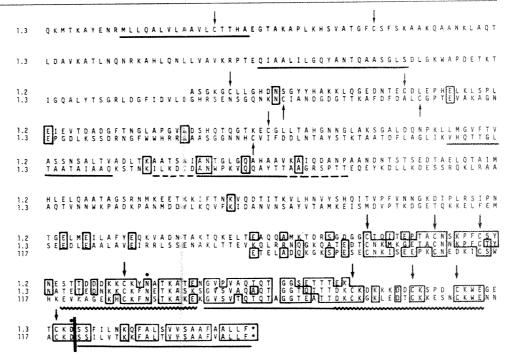

Fig. 1 Nucleotide sequences of ILTAT 1.2 and 1.3 cDNAs compared with the VSG 117 cDNA sequence as reported by Boothroyd et al. 18. Sequence determinations were carried out using the methods of Sanger<sup>30</sup> and Maxam and Gil-bert<sup>31</sup>. Most areas were verified two to four times by sequence overlaps. (Sequencing strategy and duplicate autoradiograms of sequencing gels are available on request.) The three sequences are aligned to maximize nucleotide homologies; this necessitated treating two different triplets in the coding region of VSG 117 as insertions relative to ILTATs 1.2 and 1.3 and four different locations in the 3' untranslated region of VSG 117 as deletions relative to ILTAT 1.3. The boxed regions indicate nucleotide homologies within the last 330 nucleotides. No significant homologies were detected before this region. The asterisk shows the termination codons. The region between the vertical bar and the asterisk codes for a 23-amino acid hydrophobic tail (see Fig. 3).

Fig. 2 Nucleotide sequences of ILTAT 1.1 and ILTAT 1.4 cDNA aligned to maximize the homology that occurs near the 3' end of ILTAT 1.4 cDNA. This necessitated treating one triplet in ILTAT 1.1 as an insertion relative to ILTAT 1.4. Sequences were determinined by the method of Maxam and Gilbert<sup>31</sup> Boxed regions indicate homologies within the last 100 nucleotides of ILTAT 1.4 cDNA. No significant homologies were detected before this region. The region between the vertical bar and the asterisk codes for a 17-amino acid hydrophobic tail (see Fig. 5).

3 Amino acid sequences ILTAT 1.2, ILTAT 1.3 and VSG 117 as deduced from the nucleotide sequences shown in Fig. 1. The C-termini of ILTAT 1.3 and VSG 117 are indicated by an asterisk. Boxes show amino acid homologies. Horizontal and wavy lines underneath the sequences indicate hydrophobic or uncharged hydrophilic regions, polar and respectively. Broken lines indicate regions that are uncharged polar or hydrophilic in one sequence but not in the other. Arrows indicate the cysteine residues. Dots show two glycosylation sites in VSG 117<sup>26</sup> The large vertical bar indicates the proposed cleavage site of a 23-amino acid hydrophobic tail from the nascent VSG.

sequence was then aligned to maximize homology with the other two sequences. The homology among the three cDNAs starts  $\sim$ 330 nucleotides before the termination codon and extends through the 3' untranslated region to the poly(A) terminus at the 3' end. Based on this alignment, the ILTAT 1.2 cDNA sequence ceases  $\sim$ 140 nucleotides before the termination codon.

The cDNA sequences of VSG 117 and ILTAT 1.3 both contain the 3' untranslated sequence between the termination codon and the poly(A) region (although the VSG 117 sequence seems to stop two nucleotides before the poly(A) region). These two 3' untranslated regions are virtually identical except for four deletions of 1, 3, 7 and 13 nucleotides in VSG 117 (or four insertions in ILTAT 1.3). The remaining 59 nucleotides in both sequences differ at only two positions.

The ILTAT 1.1 sequence (Fig. 2) also includes the 3'-terminal poly(A) region of the mRNA. The distance from the termination codon to the poly(A) in this case is 84 nucleotides. Alignment of all three untranslated regions to maximize homology (not shown) reveals that 42 positions are identical in the three VSG mRNAs, mostly near the poly(A) end. The significance of these observations is unclear but it does seem that portions of the 3' untranslated region do not tolerate much mutational drift. Similar sequence conservation has also been observed in the 3' noncoding region of different haemagglutinin genes of influenza virus RNA<sup>22</sup>. In contrast, the different mammalian  $\beta$ -globin genes have a high degree of sequence divergence in this region<sup>23</sup>.

Aside from the 3' untranslated region and the last three codons of the coding region, ILTAT 1.1 cDNA does not possess distinctive homology with the cDNAs of ILTAT 1.2, ILTAT 1.3 and VSG 117 shown in Fig. 1. However it does have similarities to ILTAT 1.4 cDNA. As aligned in Fig. 2, 61 of the last 100 nucleotides of ILTAT 1.4 are the same as the corresponding nucleotides in ILTAT 1.1. On this basis, the ILTAT 1.4 cDNA stops ~123 nucleotides before the termination codon. Therefore if this homology extends to the termination codon of ILTAT 1.4 coding sequence, it comprises ~225 nucleotides (or 75 codons).

### Amino acid sequences of VSGs are conserved near the C-terminus

Figure 3 compares the deduced amino acid sequences of ILTATs 1.2, 1.3 and VSG 117. These comparisons indicate that amino acid homologies near the C-terminus parallel and extend beyond the nucleotide sequence homologies noted in Fig. 1.

Furthermore, many of the amino acid changes near the C-termini are conservative in that an amino acid of similar polarity has been substituted. Generally, the C-terminal 105 amino acids of all three VSGs are highly conserved, the next 15 positions are less conserved, and a comparison of ILTAT 1.2 and ILTAT 1.3 through the next 390 amino acids towards the N-terminus reveals no significant amino acid homology (although there may be some conservation of domains as discussed below).

Figure 4a illustrates the common features of the three sequences. Within the highly-conserved C-terminal 105 amino abids are eight cysteine residues whose relative positions in the three VSGs are constant. This feature is very similar to that of the influenza virus surface glycoprotein, haemagglutinin, which also undergoes antigenic variation and contains eight invariant cysteines in the last 100 amino acid residues<sup>24</sup>. Air and Hall<sup>25</sup> have examined 35 different haemagglutinins of 17 different influenza subtypes and found that the cysteine residues are invariant throughout the entire protein. This suggests that disulphide linkages have an integral role in maintaining a general three-dimensional conformation of variants of both trypanosome VSGs and influenza haemagglutinins.

The last 23 codons of the ILTAT 1.3 and VSG 117 coding sequences specify a very hydrophobic region; seven of these amino acids are different in the two sequences but only one

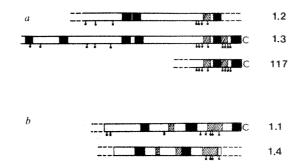

Fig. 4 Summary of the conserved features of a, ILTATs 1.2 and 1.3, and VSG 117 and b, ILTATs 1.1 and 1.4. C indicates the C-terminus; solid boxes are hydrophobic or uncharged polar regions; cross-hatching indicates highly hydrophilic regions; \$\ddot\$, cysteine residues. Broken horizontal lines represent regions for which no sequence information is available.

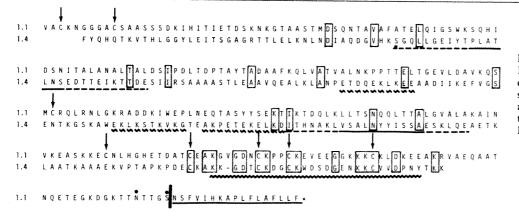

Fig. 5 Amino acid sequences of ILTAT 1.1 and ILTAT 1.4 as deduced from the nucleotide sequences shown in Fig. 2. Symbols are the same as for Fig. 3. The C-terminal hydrophobic tail in ILTAT 1.1 is 17 amino acids long.

change involves a charge difference at neutral pH. Boothroyd et al. 18 and Holder and Cross 26 reported that this 23-amino acid hydrophobic sequence is not present in the mature VSG based on C-terminal amino acid analysis of VSG 117. Furthermore, they found that the C-terminal residue is glycosylated. (The cDNA sequence of both ILTAT 1.3 and VSG 117 indicates that this terminal residue is aspartic acid, which implies an unusual glycosylation linkage.) The deduced ILTAT 1.3 amino acid sequence is identical to the VSG 117 sequence at this proposed cleavage and glycosylation site; this suggests that both proteins undergo similar processing events. The hydrophobic C-terminal sequence is preceded by a 25-26-amino acid region that is extremely hydrophilic and contains four of the invariant cysteine residues. This hydrophilic region is preceded by a conserved uncharged polar region of 17-18 residues that, in turn, is preceded by another hydrophilic region containing the other four invariant cysteine residues. The amino acid sequences then begin to diverge and very little homology is detected beyond 120 amino acids from the C-termini. Nevertheless, as Fig. 4a shows, ILTAT 1.2 and ILTAT 1.3 are similar in this divergent region in that three more sulphydryl residues and two additional uncharged polar regions occur in the same relative locations.

Figure 5 compares the deduced amino acid sequences of ILTATs 1.1 and 1.4 and Fig. 4b illustrates their common features. Although clearly similar near the C-termini, these two VSGs are less homologous than the other three. The positions of the four cysteine residues closest to the C-termini are conserved within a very hydrophilic region, similar to the other VSGs. But ILTAT 1.1 has additional cysteines further upstream that are not present in ILTAT 1.4. In addition, these two VSGs do not seem to have within their homology a distinctly conserved uncharged polar region flanked by two hydrophilic regions containing cysteines, as do the others.

ILTAT 1.1 has a very hydrophobic C-terminus as do ILTAT 1.3 and VSG 117. As inferred from other data<sup>26</sup> on VSG C-terminal amino acids, the last 17 amino acids are not present in the mature ILTAT 1.1. A comparison of this 17-amino acid hydrophobic 'tails' with the 23-amino acid hydrophobic 'tails' of ILTAT 1.2 and VSG 117 shows two similar features in addition to the hydrophobicity. All three terminate with Leu-Leu-Phe and possess a lysine seven residues removed from the proposed cleavage and glycosylation site. The significance, if any, of these similarities must remain speculative.

In summary, the C-terminal homologies of all five VSGs shown in Figs 3-5 preserve the occurrence of a C-terminal hydrophobic domain and the positions of either four or eight cysteine residues within very hydrophilic regions, suggesting that these regions are required for formation of a general three-dimensional structure. No sequence homologies larger than two amino acids occur within the N-terminal portions of the glycoproteins.

#### VSG subsets based on C-terminal homology

The above discussion suggests that VSGs can be classified into subsets based on C-terminal homology, much the same as the isotype classification of immunoglobulins (IgM, IgG, etc.) even

though the mechanisms of VSG and immunoglobulin gene expression are different 15,27,28. This possibility is substantiated by a recent report 26 of the amino acid sequences of tryptic glycopeptides at the C-termini of VSG 117 and four other VSGs. These sequences and the corresponding ILTAT sequences are listed in Fig. 6. Clearly, the nine immunologically distinct VSGs for which C-terminal information is available fall into two groups based on these sequences. Holder and Cross 26 obtained sequences of internal glycosylated tryptic fragments and these sequences generally support the same grouping into two subsets. Similarly, genomic DNA hybridization experiments using the Southern procedure also support the conclusion that there are sequence subsets of VSGs 15.28. In low-stringency hybridization conditions, C-terminal fragments of VSG cDNA hybridize to many regions in the genomic DNA; under high stringency, or using a cDNA containing N-terminal sequences, only one or a few coding regions are detected.

Finally, the genomic DNA hybridization experiments have indicated that at least two different types of DNA rearrangements occur around most, if not all, VSG coding sequences in the trypanosome genome <sup>14,18,29</sup> and may be involved in the mechanism of VSG expression. In some cases, an 'expression-linked extra copy' (ELEC) of a VSG gene occurs in cells expressing that gene<sup>18,29</sup>; in other cases, complex DNA rearrangements beyond the 3' untranslated region of the gene seem to occur, rather than an ELEC<sup>14,18,29</sup>. These two different types of DNA rearrangement do not correlate with the two different sequence homology subsets. For example, VSG 117, ILTAT 1.2 and ILTAT 1.3 belong to the same VSG sequence subset but an ELEC is associated with VSG 117 expression while 3'-distal rearrangements occur next to the ILTAT 1.2 and 1.3 coding sequences.

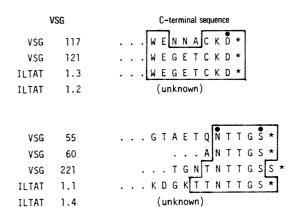

Fig. 6 Comparison of the C-terminal amino acid sequences of nine different VGSs (taken from Figs 3 and 5 and ref. 26). The exact C-terminal sequences of ILTATs 1.2 and 1.4 are unknown but they are placed in their respective groups on the basis of sequence homologies further into the protein, as shown in Figs 3 and 5. \*, C-termini; ●, glycosylation sites described in ref. 26.

We thank J. R. Young, P. A. O. Majiwa and R. O. Williams for providing plasmids containing the ILTAT cDNAs and Edward Heath for critical reading of the manuscript. The research was supported by USPHS grant AI 16950 and NSF grant PCM76-1341. A.C.R.-F. is supported by USPHS postdoctoral grant AM 07018.

### Is a bi-stable beam responsible for the complex radio structure of 3C133?

#### D. W. Robson

University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire SK11 9DL, UK

It is generally assumed that the extended lobes of radio emission found in many extragalactic sources are powered by oppositely directed supply beams of relativistic particles emanating from the central galactic nucleus<sup>1,2</sup>. The complexity and asymmetry of the structure in many sources has, however, led to speculation of a 'flip-flop' beam mechanism<sup>3,4</sup> where energy is supplied alternately to each radio lobe. Recent high resolution observations of the radio structure of 3C133 reveal a complex structure in which rotation of the source axis may have uncovered evidence for such a bi-stable nature of the energy supply. There are, however, several difficulties in such an interpretation.

The source was observed at 1,666 MHz for 13 h in August 1980, using five telescopes of the multi-telescope radio linked interferometer (MTRLI) at Jodrell Bank<sup>5</sup>. The data have been analysed by CLEAN and closure phase techniques<sup>6</sup>. The results are presented as a contour map in Fig. 1 and the main parameters of the components are summarized in Table 1. A restoring beam of 0.4 arcs, rather than the full resolution of 0.25 arc s, has been used to display the extended regions of low surface brightness.

There are four main regions of radio emission. An unresolved central component (C) is coincident with a 21st magnitude galaxy of redshift 0.28 (ref. 7). There is only a single component (D) to the west, but there are two to the east. One of these (B) is very diffuse, and the other (A) is compact and is connected to the nucleus by a narrow jetlike feature. Emission from the heads of all four components has been detected in observations of lower dynamic range with the Cambridge 5-km telescope at 15.4 GHz (ref. 8).

The lack of reflection symmetry in the structure of 3C133 is difficult to explain in terms of twin supply beams which form outer lobes at 'working surfaces' where the beams impinge on the external medium<sup>1,2</sup>. Any such explanation assumes that there have been at least two outbursts from the central object. In addition, a contrived situation is required in which motion of the galaxy through the external medium9 is coupled with either relativistic doppler effects<sup>10</sup>, beam instabilities<sup>11</sup> or an anisotropic distribution of electron pitch angles12 to account for the misalignments and number of observed components.

If the outer components were formed at different times, their morphologies might be used as indicators of their relative ages. In such a basis, the compact component A would be the oungest (and this is supported by the still evident jet), the more extended component D would be of intermediate age, and the diffuse component B, which resembles an outer lobe of well evolved source, would be the oldest. There may thus have been three outbursts of activity in 3C133, and as none of the components has a companion of similar age on the opposite side of the nucleus, these outbursts may have been fundamentally one-sided rather than symmetric in nature.

If this is so, the misalignments of the outer components could be explained by a rotation of the source axis similar to that observed in other sources 13,14. The brightness distributions across the heads of the outer components are all markedly asymmetric and have their peaks offset in a manner suggestive of clockwise rotation. This implied sense of rotation is substantiated by the observation that the jet is directed to the northern edge of component A.

While it is possible to envisage a one-sided beam which has swung through an angle  $>360^{\circ}$  and has had long quiescent periods between the outbursts, the overall configuration of the

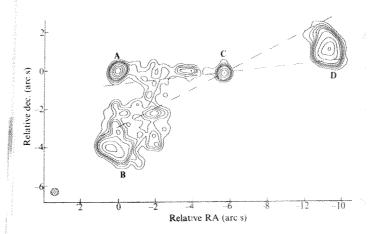

Fig. 1 The MTRLI map of 3C133 at 1,666 MHz. North is to the top and east is to the left. The restoring beam of 0.4 arcs is shown as a shaded circle to the bottom left. The contours are 2, 4, 6, 8, 10, 15, 30, 50, and 75% of the peak brightness of 225 mJy per beam. The broken lines drawn as a guide for the eye are in position angles 94° and 111°.

<sup>\*</sup> Calculated from the source redshift for an Einstein-de Sitter cosmology with  $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ .

source and the run of position angles subtended by the outer components (Table 1) can be more readily explained by a one-sided beam which has rotated through ~35° and has undergone two 180° flips in direction.

The possibility of a bi-stable beam mechanism has been suggested by recent dynamical modelling<sup>15</sup> of an initially spherically symmetric ejection of plasma from the neighbourhood of a supermassive black hole which is embedded in a flattened confining gas cloud. Calculations show that a slight displacement of the black hole from the gas cloud centre will form a one-sided jet along the direction of easiest escape. If the black hole oscillates through or rotates around the gas cloud, there could be a periodic reversal in the direction of the jet.

The observational data allow limits to be set on the time scales of precession and beam reversals for 3C133. From Fig. 1, the position angles of components A and B (measured from C) differ by ~35°, but any bending of the jet is ≤2°. Therefore, if the rotation of the jet is uniform in the plane of the sky, the rotation period  $(T_R)$  must be  $>(360^\circ/2^\circ)\times$  (jet travel time from components C to A), that is,  $>2\times10^7$  yr. The extent of the transverse elongations of components B and D imply that the interval between flips is  $\sim 0.05 T_R$ , that is,  $> 10^6$  yr which is

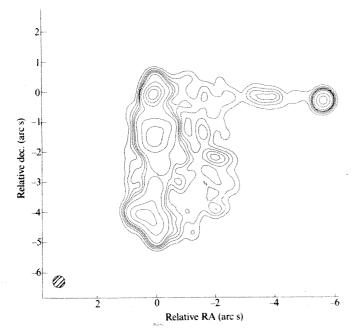

Fig. 2 MTRLI map of 3C133 after the D component has been reflected through the central component. The contours and the restoring beam are the same as for Fig. 1.

consistent with time periods of rotation and z oscillation of galaxies as would be implied by the Wiita and Siah model. In Fig. 2, the major effects of the beam reversals have been artificially removed by reflecting the D component of Fig. 1 through the central component to produce a near-continuous ridge of emission. If the small gaps between the components are due to the evacuation of new channels by the beam, the time scale for the reversal is  $\sim 0.02 T_R$  and the component re-evacuation speed is  $\leq 0.25c$ .

At first sight, the radio structure of 3C133 apparently provides the strongest observational evidence for the existence of a bi-stable or 'flip-flop' beam mechanism. There are, however, two main difficulties with such an hypothesis.

First, if the ordering of relative ages is correct, then the measured flux densities given in Table 1 indicate that the oldest components are the most luminous. If the greater size of the older components is attributable to adiabatic expansion<sup>16</sup>, then their past luminosities would have been up to several hundred times greater than at present, implying that the energy supply from the galactic nucleus has decreased dramatically with time over the three outbursts.

Second, the derived beam reversal time scale implies that the age of component B is  $> 2 \times 10^6$  yr. There is therefore a problem in explaining the detection of emission from all the outer components at 15.4 GHz, as the synchrotron lifetimes of the electrons radiating predominantly at this frequency are  $\sim 3 \times$ 10<sup>5</sup> yr if the magnetic fields and electrons are in equipartition. This difficulty may be overcome if the rotation is non-uniform, as might be expected if the beams are collimated in the vicinity of a Kerr black hole whose spin axis was initially misaligned with that of the surrounding galaxy<sup>17</sup>. If the axes initially differed by ~40°, but have now swung into near alignment because of the interaction between the angular momenta of the black hole and of the galactic material, then the rotation would originally have been much more rapid, removing the apparent discrepancy between the implied component ages and the synchrotron lifetimes. The similarity of the angles subtended by the components would then imply that the time between beam reversals would have lengthened considerably.

If both the beam luminosity and the length of time that the components are powered have varied, then it seems fortuitous that the outer components all lie at similar distances from the nucleus. Perhaps a simpler solution to the difficulties might be that particle reacceleration occurs in the outer components to produce a delayed brightening of the outer heads after the beam is switched off. It is, however, difficult to envisage such a physical process, and it seems ironic that the need for in situ particle acceleration in outer lobes of radio sources was the reason why beams providing a continuous supply of energy were originally postulated.

Despite some problems, a bi-stable beam mechanism seems to offer the most natural explanation for the unusual and complex structure of 3C133. Note, however, that the evidence for such a mechanism is only conspicuous because of the rotation of the source axis. To what extent such switching occurs in normal co-linear sources is unclear, but such a mechanism could explain the complex sub-structure seen in many sources<sup>18</sup>, and the one-sided emission of the more compact and possibly younger D2 objects<sup>19</sup>.

I thank Dr D. Stannard and other colleagues at Jodrell Bank for helpful discussions and the SERC for a studentship.

### Unidentified features in the spectrum of Triton

G. H. Rieke, L. A. Lebofsky, M. J. Lebofsky & E. F. Montgomery

University of Arizona, Tucson, Arizona 85721, USA

Water frost has been identified on the surfaces of the satellites of Jupiter<sup>1</sup>, Saturn<sup>2</sup> and Uranus<sup>3,4</sup>; methane frost is dominant on . However, although the IR spectrum of Triton, the largest satellite of Neptune, is similar to that of methane or methane frost<sup>8</sup>, this identification is not consistent with all the available data<sup>9,10</sup>. We have now used the Multiple Mirror Telescope (MMT) to obtain an improved IR spectrum of Triton. Our observations show features that are not in detailed agreement with the identification of methane, although the general spectral behaviour that led to this identification is confirmed. A satisfactory identification of the surface and/or atmospheric composition on Triton does not yet seem possible.

Observations were made with the circularly variable filter in the MMT IR photometer. The wavelength calibration and spectral resolution of 1% were determined by laboratory measurements of gaseous discharge lamps and were confirmed by measurements of P $\beta$  and B $\gamma$  from the planetary nebula NGC7027. All observations were made through a 9 arcs aperture and with reference beam spacing of 20 arc s. Care was taken to ensure that neither the measurement beam nor the reference beams were contaminated by light from Neptune. Observations were carried out on 24.4 April, 13.4 June and 16.4 June 1981 (UT), in all cases very close to maximum elongation of Triton from Neptune. Atmospheric corrections were determined by measuring the solar type star 58 Oph at equal elevation to Triton.

Figure 1a shows the spectrum of Triton, Fig. 1b the same data smoothed to 4% spectral resolution. The error bars are  $\pm 1$  s.d. and have been estimated from the reproducibility of repeated spectral scans, on the assumption that the noise level (dominated by detector noise) was the same for all wavelengths. The longest total integration time was devoted to the 1.94-2.12-µm region of the spectrum; hence, the signal-to-noise ratio is highest there.

The new data are in satisfactory agreement with previous narrow-band photometry of Triton<sup>9</sup>. A previous fully sampled but very noisy spectrum of Triton<sup>9</sup> agrees in broad outline with the new data but seemed to show high resolution structure that is only partially confirmed by the higher quality data presented here

The data show the broad absorption near 2.35 µm which led to the previous identification of methane<sup>8</sup>. There is also a narrower, but resolved, absorption at 2.10 µm, and possibly an unresolved absorption at 2.00 µm, an absorption or absorption edge near 1.94 µm and a broad but shallow absorption at 1.65 µm. These latter three features are at a 2-3 s.d. level of significance and need to be confirmed at higher signal-to-noise ratio. In addition, the very strong and broad absorption from 3 to 4 µm (ref. 11) is confirmed by a new measurement with the Infrared Telescope Facility, which shows the average reflectivity between 3.0 and 3.8  $\mu$ m to be  $0.48 \pm 0.05$  times the reflectivity at 2.2 µm. In the visible, the spectrum of Triton is featureless except for a general decrease in reflectivity towards the  $UV^{10,12}$ 

The features in the spectrum of Triton could arise directly from the surface material or from gases in a tenuous atmosphere, or from some combination. The lower limit of 0.19 for the albedo12 suggests that the surface may be at least partially frost-covered. Therefore, we have considered the reflectance spectra<sup>13</sup> of four frosts that are among the most likely candidates for this environment (Fig. 1): H<sub>2</sub>O, CH<sub>4</sub>, NH<sub>3</sub> and H<sub>2</sub>S. These spectra have been smoothed to correspond to a resolution of ~1%. None of the frosts provides a satisfactory match to the spectrum of Triton. CH4 and H2S frosts are probably also too reflective from 3 to 4 µm to be consistent with the observations of Triton. We have failed to find a satisfactory match to the spectrum of any other frost.

At the temperature appropriate for the surface of Triton, only a few molecules have sufficiently high vapour pressure to form an atmosphere. Of these, the only two which are likely to be present on the basis of normal solar abundances and which are spectrally active in the 1.6-2.4 μm region are CH<sub>4</sub> and CO. Either of these gases can account for the broad absorption near  $2.35 \ \mu m$ ; however, CH<sub>4</sub> would then produce an absorption of nearly equal strength from 1.65 to 1.8  $\mu m,$  and CO would not be

absorbing between 3 and 4  $\mu$ m. Recent studies<sup>10</sup> have placed an upper limit of  $1 \times 10^{-3}$ amagat on the atmospheric CH4 abundance on Triton. The absence of any absorption centred at 1.7 µm in our spectrum places an independent limit of  $1.5 \times 10^{-3}$  amagat on the atmospheric CH<sub>4</sub> abundance. The absorption feature near 2.35 μm is two to three times stronger than would correspond to an atmosphere of CH4 at these limits. It therefore seems unlikely that CH<sub>4</sub> as either gas or solid is the dominant spectrally active constituent on Triton.

A combination of surface and atmospheric absorptions might resolve some of these discrepancies-for example, many hydrated minerals and frosts are very dark between 3 and 4  $\mu m$ , so that a CO (and possibly methane) atmosphere over a rocky or frosty surface might fit the data. However, the absorption feature at 2.10 µm remains an anomaly. Very few of the

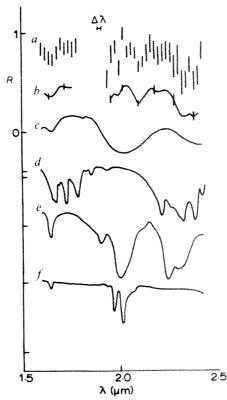

Fig. 1 Reflectivity of Triton and selected frosts. a, Arbitrarily normalized reflectivity of Triton at the original spectral resolution of 1.0%. molecules likely to be abundant on Triton produce features at this wavelength, and the few which do (such as N<sub>2</sub>O) do not match the remainder of the spectrum satisfactorily.

The surface compositions of small bodies in the outer Solar System have generally followed a simple pattern: a single material from a small list of those likely to be abundant dominates their IR reflection spectra. Triton seems to violate this pattern. Further improvements in the observations and in the laboratory spectra of candidate materials will be required to analyse the surface of Triton.

The Multiple Mirror Telescope Observatory used for the present research is a joint facility of the University of Arizona and the Smithsonian Institute. The photometry at 3.5 µm was taken with the Infrared Telescope Facility, which is operated by the University of Hawaii under contract from NASA. Assistance with the observations was provided by B. Kindred and B. Light. We acknowledge helpful discussions with D. Cruikshank, U. Fink and G. Sill. This work was supported by NASA.

### Morphology of iodine-doped polyacetylene

M. Rolland\*, M. Aldissi†, P. Bernier\*, M. Cadene\* & F. Schue†

\* Groupe de Dynamique des Phases Condensées and † Laboratoire de Chimie Macromoléculaire, Université des Sciences et Techniques du Languedoc, Place E. Bataillon-34060 Montpellier-Cedex,

Although the synthesis of polyacetylene powders was first carried out many years ago, Ito et al.1 have only recently obtained films which can be doped with various chemical species, such as I2, SbF5 or Na, K, giving p or n type semiconductors. These and other properties, such as its optical bandgap<sup>2</sup> ( $E_g \approx 1.5 \text{ eV}$ ) have made polyacetylene an interesting material for study3mechanical stretching ability, for example, leads to partially oriented fibrils and an electrical conductivity anisotropy  $\gamma_{\parallel}/\gamma_{\perp} \simeq 10$  has been measured with  $\gamma_{\parallel}$  reaching  $3 \times 10^3 \, \Omega^{-1} \, \mathrm{cm}^{-1}$  when highly doped with AsF<sub>5</sub>; roughly 12 orders of magnitude higher than the value measured on undoped cis (CH)<sub>x</sub>. Polyacetylene is available in two isomeric configurations (cis and trans, Fig. 1). More than 98% cis isomer is obtained if the synthesis is performed at low temperatures (-78 °C) but it is not thermodynamically stable and becomes trans on increasing the temperature, the total transformation occurring when T > 100 °C. Any doping process induces a partial cis/trans isomerization<sup>8</sup>. The exact conduction mechanism is poorly known: the localization and nature of the doping species have been widely discussed. Here we investigate, using scanning electron microscopy, the behaviour of the morphology of (CH), films when the dopant concentration varies. Starting from the fibrillar structure we have observed the formation of aggregates and a uniform melt of various globular features at high doping levels. Our results yield information on how the electrical conductivity takes place in these non-uniform materials.

Acetylene was polymerized, using Shirakawa's technique1, on the surfaces of a glass reactor. The essential experimental conditions are: solvent, toluene; Al/Ti ratio of 4; catalyst concentration, 0.3 Ti mol 1<sup>-1</sup>; ageing of catalyst, 1 h; temperature, -78 °C; acetylene pressure, 1 atm. The 100-μm thick films obtained were carefully washed in toluene. The cis-rich (CH)<sub>x</sub> samples were doped with iodine vapour in equilibrium with its liquid phase at 25 °C, samples were then pumped for 2 days to remove the interfibrillar non-fixed dopant molecules. The dopant concentrations were evaluated from the weight increase. At low doping levels, the concentration y, defined by (CHI<sub>v</sub>)<sub>x</sub>, is a mean value over the whole sample, taking into account the fact that the macroscopic diffusion coefficient of iodine in  $(CH)_x$  films is  $\sim 10^{-8}$  cm<sup>2</sup> s<sup>-1</sup>. All our observations were made in the middle of the section of the films to avoid any boundary effect, and the samples were fractured under liquid nitrogen to avoid stresses.

Gold coating was performed by sputtering, the thickness of the obtained film being in the range 50-100 Å. Scanning electron micrographs were performed using a JEOL JSM 35 instrument working with an electron beam energy of 20 keV, and a current <1 nA to avoid any radiation damage.

On the first micrograph (Fig. 2a) we observe the fibrillar structure of the undoped cis-rich (CH)<sub>x</sub>, where a few globular features appear. For  $y \approx 10^{-2}$  (Fig. 2b) we note white areas as well as the formation of large aggregates. With y = 0.03 (Fig. 2c) we observe: (1) an extension of the large aggregates; (2) a regression of the fibrillar structure, which seems to be masked: (3) the appearance of many small white points. We also observe that the true volume occupied by the material is enhanced along Fig. 2a to c. For y = 0.14 (Fig. 2d), all the platelets and fibrils are recovered with the white points whose size has increased. With y = 0.3 (Fig. 2e) the observed background is very homogeneous and spattered with large white points.

It has been shown elsewhere that the fibrillar structure is modified when the dopant concentration increases, so we performed another experiment to find out whether the fibrils were masked or destroyed. A (CH)<sub>x</sub> film was iodine doped up to y = 0.30 and then the dopant was extracted by plunging the doped film in toluene with granular silver to form AgI. After a week, the dopant concentration in the film had fallen to y = 0.1: Fig. 2f shows clearly that the fibrillar structure remains, although their length is reduced and their diameter enhanced; it seems that the y = 0.1 dopant concentration only applies inside

Using a CF<sub>3</sub>SO<sub>3</sub>H dopant we do not observe white points but a considerable increase in size of the fibrils at high dopant levels leading to the formation of islands.

We have investigated the dopant diffusion mechanism during the doping process of (CH), films and shown that the usual diffusion Fick law's cannot explain the measured dopant profiles through the film—an additional process related to a chemical interaction between dopant molecules and (CH)<sub>x</sub> fibrils must be involved which must include two kinds of dopant inhomogeneity: (1) A macroscopic inhomogeneous distribution of doping molecules, as presented above, which disappear on highly doped samples. (2) An inhomogeneity inside the fibrils, which persists for a long time, due to the very low diffusion of

Fig. 1 Cis (a) and trans (b) isomeric configurations of polyacetylene.

dopant molecules in the crystalline parts of the (CH)x films, but leads to a rapid production of the observed platelets and to an increase of the diameters of the remaining fibres.

Finally note that the y values for Fig. 2b-e are an approximative evaluation, the uncertainty is due to the dopant inhomo-

geneity through the sample discussed above.

Recent experiments10 and I2 and SbF5 doping trans (CH)x seems to produce a more homogeneous doped material but these SEM observations were performed at the film surfaces and not on the cross-section. We have also observed that the surface composition and morphology are uniform at all doping rates9, and nearly the same on either side of the film.

To correlate our observations with the electronic transport properties of doped (CH)x, we have plotted on Fig. 3 the electrical conductivity and the corresponding activation energy against the dopant content3 which exhibits a semiconductor to metal transition near 1-3%, depending on the dopant species. At lower dopant levels Rice<sup>11</sup> proposed a theoretical model for the electrical conductivity based on the assumption of a very inhomogeneous distribution of the doping species inside the fibrils. In all cases the conducting process was attributed to an extrinsic semiconducting process where an acceptor A or a

Typical behaviour of electrical conductivity and deduced Fig. 3 activation energy of doped (CH)x (from ref. 3).

donor A+ lying near a chain bring, by thermal activation, a carrier which can be delocalized along the chain.

Looking at our present data, taken at various doping levels, some previous assumptions should be revised.

- (1) At very low dopant concentrations  $y < 10^{-2}$  (Fig. 2b) the presence of fibrils coated with doping species seems likely. However, a chemical reaction between the bulk material and the doping species leads to a rapid production of the observed platelets.
- (2) For higher concentrations an important modification of the polyacetylene morphology takes place: fibrils seem modified. In addition, the increasing size and number of white globules with increasing dopant concentration (Fig. 2e) suggest a percolation process to explain the conductivity mechanism (Fig. 3). The slight conductivity increase observed above y =0.03 would be due to the variation of the size and conductivity of the elementary clusters. However, these results are obtained when cis (CH), film is doped at room temperature (25 °C) using the dopant vapour phase in equilibrium with its solid one. We have also verified that similar results are obtained by doping with a pentane solution of iodine if the dopant concentration is high enough.

Consequently we can analyse these observations by way of an inhomogeneous doping process: vapour iodine condense on the fibrils and rapidly react with the polymer to give very highly doped regions. The percolation process could be a consequence of this dopant concentration inhomogeneity in the sample.

These assumptions are also compatible with the effect of dopant concentration on the thermoelectric power and far IR absorption. Note that such a percolation model, implying conductivity between metallic particles embedded in a dielectric continuum, has also been proposed by Mortensen et al.

In conclusion our first experiments, using scanning micrograph analysis, on the doping effect on the polyacetylene morphology indicate that, at very low  $(y \le 10^{-2})$  dopant concentration, the dopant may produce the same effect as that of an impurity on an inorganic classical semiconductor of increasing the carrier number; at higher concentration, that is, around the semiconductor to metal transition region and above, the fibrillar structure seems modified.

Elsewhere the fibrillar structure evolves leading to short fibrils, the diameter of which is largely increased. Consequently the morphology of the doped material strongly depends on the polymerization and doping conditions.

## Fusion of pyrope at high pressures and rapid crystal growth from the pyrope melt

Eiji Ohtani\*, Tetsuo Irifune†‡ & Kiyoshi Fujino\*

\* Department of Earth Sciences, Faculty of Science, Ehime University, Matsuyama 790, Japan † Department of Earth Sciences, Faculty of Science, Nagoya University, Nagoya 464, Japan

Pyrope Mg<sub>3</sub>Al<sub>2</sub>Si<sub>3</sub>O<sub>12</sub> is the magnesium end member of the pyralspite garnet series, which is an important constituent of the upper mantle. Melting experiments at high pressure are necessary to clarify the chemical heterogeneity in the deep mantle and the origin of various magmas. Some authors have suggested the possibility of the pressure-induced structural change of silicate melts and discussed its importance on the magma generation and the differentiation in the mantle<sup>1,2</sup>. We report here melting experiments on pyrope at pressures up to 10 GPa as a first stage in extending the pressure range of model systems for the upper mantle and examining the possibility of the pressure-induced structural change of the melt at high pressure. The correlation between the melting curve and the change of the quenched phases from the melt is the first evidence of a structural change of the pyrope melt at high pressure.

Pure pyrope synthesized at 6 GPa and 1,250 °C was used as the starting material. This powder was directly packed in a graphite capsule which is used as a heater. An MA8-type high-pressure apparatus<sup>3</sup> was used. Pressure calibration was

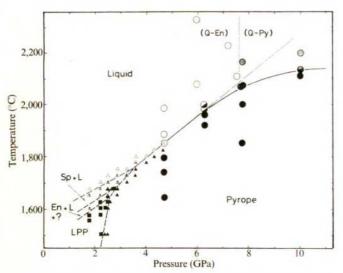

Fig. 1 Melting curve of pyrope up to 10 GPa. The data below 4.7 GPa are from ref. 5 and above this pressure are from the present work. LPP, low pressure phases (mixture of sapphirine, alumonous enstatite, and sillimanite); En+?+L, aluminous enstatite, undetermined phase (sillimanite or sapphirine?) and liquid; Sp+L, spinel and liquid; ●, pyrope recrystallized without melting; O, quench crystal of aluminous enstatite formed from the melt by quenching (Q-En) (glass is also observed below 6.5 GPa); O, quench crystal of pyrope formed from the melt by quenching (Q-Py). The pressure at the change of the quenched phase is shown as a dotted line. The light dashed curve is the extrapolated melting curve fitted to data below 7.0 GPa with the Kraut-Kennedy equation. The curve is expressed as  $T(K) = 1,708 (1 + 9.5\Delta V/V)$ , where  $\Delta V/V$  is calculated using the Birch-Managhan equation of state with the available low-temperature bulk modulus and its pressure derivative9. The discrepancy becomes very large above 7.5 GPa.

†Present address: Department of Geology and Mineralogy, Faculty of Science, Hokkaido University, Sapporo 060, Japan.

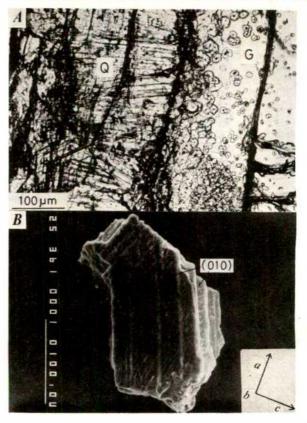

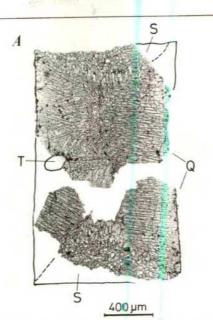

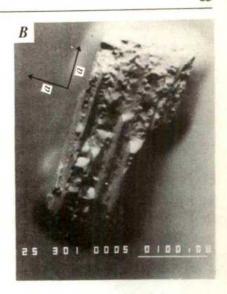

Fig. 2 A, Photomicrograph of the run product quenched from 5 GPa and 1,850 °C. The glassy part (G) and the lamellae of quench aluminous enstatite (Q) are clear. B, Scanning electron image of quench aluminous enstatite. The lamellar texture and the (010) plane are clear. The elongated direction of the lamellae does not coincide with the c-axis, and the angle between the elongated direction and the c-axis is  $69.3 \pm 0.5^{\circ}$  in this lamellar crystal. The streaks on the (010) plane are also observed in this photograph. Scale bar,  $100 \, \mu \text{m}$ .

made at high temperature using the phase boundaries of olivinespinel transition in Fe<sub>2</sub>SiO<sub>4</sub> and coesite-stishovite transition determined by a high-pressure X-ray diffraction method4. Temperature was measured by a W-W26% Re thermocouple. The quenching method was used to determine the melting curve. The furnace assembly was dried in an oven at about 150 °C for a few hours immediately before each run to avoid the effect of absorbed water on the melting temperature. Pressure was applied to the sample first, and then the temperature was brought to a desired value. Heating was limited to a few minutes to avoid the contamination by the furnace material and the thermocouple to the sample. The sample was quenched isobarically by shutting off the electric power supply. Thin sections of the run products were prepared for microscopic observation and EPMA analysis. X-ray diffraction was also used to identify the run products. Melting was recognized by microscopic observation of the texture of the run products.

Figure 1 shows the melting curve of pyrope up to 10 GPa. The results below 4.7 GPa were obtained by Boyd and England<sup>5</sup>, whereas the data above 4.8 GPa come from the present investigation. As the temperature gradient of the furnace is large; the difference of the temperatures between the central part and the end part of the furnace amounted to ~100 °C (ref. 7) only the run products around the thermocouple were selected and examined to determine the melting curve shown in Fig. 1. The present results combined with those of Boyd and England indicate that pyrope melts congruently from 3.6 to 10 GPa. The slope of the melting curve is very large, about 79° GPa<sup>-1</sup> at pressures below 7 GPa; above this pressure there is a significant decrease. The possibility that the bend of the melting curve originates from an ambiguity of the present pressure scale can be

Fig. 3 A, Photomicrograph of the run product quenched from 10 GPa and 2,200 °C. The quenched pyrope with lamellar texture (Q) is observed clearly. The recrystallized pyrope without melting (S) observed in the end part of the furnace cell is due to the temperature gradient of the furnace. T is the point of the thermocouple. B, The backscattered electron image (TOPO) of quenched pyrope. Pyrope quench crystal elongates to [100] direction. Scale bar, 100 μm.

ruled out, because we made the pressure calibration at high temperature using the phase boundaries determined by X-ray diffraction on the basis of NaCl pressure scale<sup>4</sup> and such bend of the melting curve above 7.0 GPa was not observed in the case of forsterite<sup>6</sup> and fayalite<sup>3</sup> for which the same apparatus and pressure scale were used.

The pyrope melt is quenched to a glass and quench crystal with a lamellar texture below 6.5 GPa. Above this pressure, the run products formed from the melt were aggregates of quench crystal, and the glass was not observed. The quench crystal was aluminous enstatite at pressure below 7.5 GPa. Above 7.5 Gpa quench crystals of pyrope were formed in place of aluminous enstatite.

Figure 2A shows the coexistence of glass and quench crystals formed by quenching from 1,850 °C at 5 GPa. Both the glass and the quench crystal were analysed by EPMA and found to have a pyrope composition. There is no difference in the chemistry of the quench crystal and the glass. The X-ray diffraction pattern of the quench crystal can be indexed as an orthorhombic pyroxene with a space group Pbca. According to the EPMA and X-ray diffraction analysis (Table 1), the quench crystal is an aluminous enstatite with a pyrope composition. To our knowledge, this is the first report of a pyroxene with pyrope stoichiometry. The scanning electron image (SEI) of the quenched aluminous enstatite is shown in Fig. 2B where the lamellar texture and (010) plane are clear. The elongated direction of lamellae does not coincide with that of tetrahedral chains along the c-axis of the pyroxene structure, and the angle between the elongated direction and the c-axis varies from 60° to 70° among the different sheaves of lamellae.

The quenched pyrope formed at pressures above 7.5 GPa has a lamellar texture and can be distinguished from the pyrope crystal recrystallized without melting, which is granular in texture. Figure 3A shows the coexistence of a quenched pyrope and a recrystallized pyrope. The coexistence of these two phases is one of disequilibrium and is caused by the temperature gradient in the furnace. The difference in the textures is clear. X-ray precession photographs indicate that the lamellae elongate parallel to [100] direction and the planes parallel to [100], which are assigned to {011} planes, are also observed. The backscattered electron (TOPO) image of the quenched pyrope is shown in Fig. 3B. The quench crystal from the pyrope melt changes from aluminous enstatite to pyrope around 7.5 GPa in accordance with the bend of the melting curve.

The bend of the melting curve can be explained by a volume decrease of the melt due to a pressure-induced structural change. The structural change of the melt by a shifting of Al ions from fourfold to sixfold coordination has been suggested by Waff<sup>2</sup>. Recent Raman spectrometry of the jadeite glass synthesized at pressures up to 4 GPa indicated that there was no evidence of a coordination change of Al ions7. However, this type of the structural change in the melt can be expected to occur at even higher pressure. Al ions occupy both tetrahedral and octahedral sites in aluminous enstatite, while all Al ions occupy the octahedral sites in pyrope. As has been reported, some pyroxenes transform to the garnet structure at high pressure8. Then the change of the quench crystal from pyroxene to garnet in accordance with the bend of the melting curve may suggest such a pressure-induced coordination change of ions in the pyrope melt at high pressure.

We thank M. Kumazawa for discussions and encouragement.

### Hydrazines and carbohydrazides produced from oxidized carbon in Earth's primitive environment

#### Clair E. Folsome\*, Andrew Brittain\*, Adolph Smith† & Sherwood Chang†

\* Laboratory for Primordial Biology, Department of Microbiology, University of Hawaii at Manoa, Honolulu, Hawaii 96822, USA † Life Sciences Division, NASA Ames Research Center, Moffett Field, California 94035, USA

Our ideas of the possible composition of the atmosphere of the primitive Earth have broadened markedly since Oparin's and Urey's<sup>2</sup> postulates of a highly reducing atmosphere containing hydrogen, ammonia, hydrocarbons and water. Since then, various geochemical models of the primordial atmosphere have been proposed<sup>3-6</sup>. Of importance is whether abiological organic compounds can be formed from the interactions of energy sources with nitrogen, oxidized carbon and water. Experiments involving electrical discharge<sup>5,7</sup> and bombardment with beams of He ions<sup>6</sup> of various mixtures of CO, CO<sub>2</sub>, N<sub>2</sub>, H<sub>2</sub> and H<sub>2</sub>O suggested that formic acid was the major organic product. We now report experiments using quenched spark discharges through molecular nitrogen on aqueous suspensions of CaCO<sub>3</sub> and other reactants to simulate the atmosphere/hydrosphere interface. Hydrazine and carbohydrazide are recovered in significant but low yields. Their reactions in primitive aquatic environments could have supplied a pathway for chemical evolution and the origin of life on a primitive Earth in which carbon in the fully oxidized states was available for the primary synthesis of organic matter.

Our experiments were designed (1) to supply aqueous inorganic carbon in the form of calcium carbonate to effect pH control near pH 7.5-8.0 as well as to provide dissolved CO<sub>2</sub> and dissolved CO<sub>3</sub><sup>2-</sup> anion in constant small amounts determined by the low solubility product of CaCO<sub>3</sub>, and (2) to supply Fe<sup>0</sup> to act as a scavenger for oxidizing agents. We believe that such a system corresponding to a primordial atmosphere/hydrosphere interface is suitable for assessing potential pathways for organic synthesis where carbon is in the +4 oxidation state.

Five-litre flasks equipped with a central nichrome or gold wire electrode and a high-vacuum valve were filled with 50 ml doubly distilled water, 100 mg (1.78 mmol) 400-mesh reduced iron and 100 mg (1 mmol) CaCO<sub>3</sub>. The gas phase was evacuated, purged with nitrogen and filled with 750 mm nitrogen (223.2 mmol). For some experiments, 0.5 mCi NaH<sup>14</sup>CO (specific activity 50 Ci mol<sup>-1</sup>) was added using a gas-tight syringe through an attached septum. An Electro-Technics highfrequency generator was connected to the central electrode and discharged on the water surface through a capacitatively coupled external metal ground plate. After 10-18 h, the cloudy white suspension of CaCO<sub>3</sub> became clear and the pH dropped from 8.1 to 7.0. At this time, gas chromatographic analysis of the headspace (5 ml samples at ~750 mm) showed no detectable H<sub>2</sub> or O<sub>2</sub>, traces of CO<sub>2</sub> and minute amounts of CH<sub>4</sub> in an excess of unreacted nitrogen.

Chemical analysis of both the water and particulate phases

was negative for nitriles (by pyrohydrolysis and benzidine acetate-copper(II) acetate staining) and for amino acids (by ninhydrin staining). Nitriles present in nanomolar amounts could have been detected by this method. TLC on silica gel plates revealed a single dominant organic component which was detected by iodine vapour, or by rhodamine-B staining, or as a dark spot on silica gel layers containing a 254-nm UV fluorescent dye. The product had the same  $R_{\rm f}$  values as standard carbohydrazide in four solvent systems: (1) butanol/formic acid/water, 17:1:2; (2) CHCl<sub>3</sub>/methanol/8.4 M NH<sub>4</sub>OH, 2:2:1; (3) CHCl<sub>3</sub>/methanol/12 M NH<sub>4</sub>OH, 85:15:1; and (4) CHCl<sub>3</sub>/methanol/8.4 M NH<sub>4</sub>OH, 1:4:1. Standard carbohydrazide and a related standard, semicarbazide, were obtained from the Aldrich Chemical Co.

When 0.5 mCi NaH14CO3 was included in several such quenched spark-discharge reaction mixtures, 30% of the organic 14C-labelled products migrated with R<sub>f</sub> values identical to carbohydrazide in the above TLC solvent systems, while the balance remained at the origins. (The organic carbon products remaining at the origins have not been firmly identified, although when subjected to 6 M HCl hydrolysis at 120 °C, ninhydrin-positive and UV chromatophores were released.) In one typical experiment, 1,200 d.p.m. total organic carbon per 40-μl sample  $(1.5 \times 10^6 \, d.p.m.$  per  $50.5 \, ml$  total reaction volume) were recovered after addition of 6 M HCl at 25 °C to decompose unreacted carbonate. Of this total,  $0.42 \times 10^6$  d.p.m. (28%) behaved identically to carbohydrazide on the chromatograph. If we assume both labelled NaHCO3 and unlabelled CaCO, to be equally reactive, the carbohydrazide yield was 0.38 µmol, and the total organic carbon yield 1.38 µmol. This latter value indicates conversion of 0.14% of the initial carbonate to organic carbon.

Carbohydrazides are used as intermediates in various organic synthetic reactions<sup>8,10,11</sup> and undergo many reactions similar to hydrazine. Hydrazine is implicated as an intermediate in the reactions leading to carbohydrazide formation, because carbohydrazide (III) is a major carbon-containing product and its synthesis results from reactions of hydrazine (I) with carbon dioxide via carbazic acid (II) as an intermediate 9,10:

$$\begin{array}{lll} H_2NNH_2 + CO_2 \rightarrow H_2NNHCO_2H \rightarrow H_2NNHCONHNH_2 + HOH \\ & \text{(III)} \end{array}$$

Tests for hydrazine in the water phase of these reactions were positive, as determined by TLC of its yellow p-dimethylaminobenzaldehyde azine derivative and quantitatively using the ASTM standard test D-1385-18 for hydrazine in water, and confirmed by combined gas chromatographic/mass spectrometric analysis. Table 1 presents the data for the synthesis of hydrazine in various reaction conditions. Assuming linearity, the maximal rate of synthesis was 0.83 µmol hydrazine h<sup>-1</sup>; the rate decreases after  $\sim 10$  h, coincidentally with the apparent loss of solid CaCO<sub>3</sub>.

Table 1 also summarizes data on the presence of carbohydrazide, the final pH and other observations for various combinations of reactants in quenched spark discharge experiments. Note that hydrazine is always present with carbohydrazide. Carbonate is required and the pH must be maintained near or above 7.0 during most of the hydrazine/carbohydrazide synthesis. Reduced iron is not required to scavenge oxidants, but dinitrogen appears to fulfil this role, as manifest by the relatively large amounts of nitrite and nitrate seen in all experiments. The data so far do not indicate whether solid carbonate or soluble carbonate anions are involved when CaCO<sub>3</sub> is used. If carbon is present as CO<sub>2</sub>, no hydrazine nor carbohydrazide is formed. Neither Ca2+ nor Na+ anions will lead to the synthesis of hydrazine or carbohydrazide in the absence of carbonate. When air was substituted for nitrogen, hydrazine and carbohydrazide yields were similar to the anoxic experiments. In all cases, carbohydrazide is only found when hydrazine is synthesized, supporting our suggestion that its synthesis proceeds via carbazic acid, as proposed by others9,16

These experiments show that, in anoxic prebiotic or contemporary atmospheric conditions, in the absence of molecular

A: those reaction conditions which lead to the synthesis of hydrazine and carbohydrazide. B, those reaction conditions which lead to the oxidation of molecular nitrogen. Nitrate and nitrite were measured according to ref. 15.

hydrogen: (1) molecular nitrogen can be reduced to hydrazine; (2) oxidized carbon is reduced to organic carbon products of which one-third is carbohydrazide; (3) molecular nitrogen serves as the primary oxidant scavenger, leading to the formation of nitrite and nitrate.

The significance of these simulated processes in the routes to organic matter from oxidized carbon in a mildly reducing prebiotic Earth model remains to be assessed. Nonetheless, the yields reported here, though lower than in similar systems containing methane<sup>13</sup>, are much higher than achieved earlier in systems containing fully oxidized carbon<sup>5,7</sup>. This suggests that organic synthesis in prebiotic surface environments consonant with previous models<sup>3-6</sup> merits further investigation. More productive processes may yet be found; further studies of similar heterogenous systems are underway

Southern Chile (41-56°S), in the belt of westerly winds, receives mostly heavy precipitation, reaching 8,500 mm yr near 50 °S and decreasing northwards and southwards from this latitude to ≤1,500 mm; mean January (summer) temperatures near sea level along the latitudinal gradient are 8-16 °C (refs 1, 2). Dense rain forest covers much of the region to 48 °S; south to Cape Horn, magellanic moorland prevails and rain forest becomes limited. Modern pollen measured in surface samples reflects the distribution of plant species in the vegetation. We have now applied regression equations relating present-day pollen to temperature and precipitation to fossil pollen data at Taiquemó to assess climatic conditions during the Quaternary. The results extend our previous record of the past 16,000 yr at Alerce<sup>3</sup> beyond the lateglacial to  $\sim$ 43,000 yr BP. For the 27,000-yr interval, they show mean January temperatures of 10-12 °C and mean annual precipitation centred around 1,000 mm except during the time span of ~31,000-43,000 yr BP when amounts increased to 4,000 mm. In general fluctuations correspond to the isotopic climatic reconstruction in Antarctica4 and to changes inferred from pollen data at comparable latitudes in Tasmania<sup>5-8</sup> and New Zealand<sup>9,10</sup>.

We derived temperature and precipitation data from the pollen contained in sediments in a lake basin at Taiquemó (42°10'30" S, 73°35'45" W)<sup>11</sup>. The site is located on northeastern Isla Chiloé at an elevation of 170 m, 105 km south-west of Alerce where we reported quantification of southern Chile climatic change to 16,000 yr ago<sup>3</sup>. The basin is situated at the outer edge of an end moraine that is partially cutover and occupied by remnants of Valdivian rain forest. The moraine seems to date from the middle part of the Llanquihue (Wisconsin) Glaciation, the last glacial age to affect Isla Chiloé. A 760-cm core from the basin is  $^{14}$ C dated to  $42,700 \pm 1,200$ (QL-1011) and to 42,400±1,000 (QL-1012) yr BP at the respective 700-cm and 760-cm levels; these and six additional ages establish the chronology of the core sediments.

Data for the sediments in the core (Table 1) show peat beds in the upper 200 cm and below 560 cm interbedded by gyttja. The upper bed began forming at 14,120 yr BP and the lower bed formed from ~43,000 until before 31,200 yr BP. Loss on ignition measurements indicate that percentages of organic matter in the core are lowest during the lacustrine phase between 200 and 560 cm; the sedimentation rate over the 43,000-vr interval was lowest during the latter part of this phase from 20,100 to

14,120 yr BP. Pollen influx is relatively low; averages are higher for the peat than for the gyttja, with highest values in the basal peat.

The temperature and precipitation equations were produced by stepwise regression, using normalized per cent averages of 20 pollen taxa as predictors. Although the taxa are moderately intercorrelated (maximum r = 0.69), orthogonalization of the variables failed, even after rotation, to produce a biologically convincing solution. A total of 59 composite sites (160 surface samples) was used for estimating temperature and 57 for precipitation. Addition of 33 composite sites from the rain forest of Tierra del Fuego<sup>12</sup> enlarged the data set on which Alerce estimates were based. Application of the new equations to the Alerce data gave results in agreement with trends reported previously. The new equations seem, however, to be much more sensitive to observed variations in the older pollen record at Taiquemó. The temperature equation has seven terms that explain 82% of the variance; the standard error of estimate is 0.96 °C (12% of the range of surface temperatures). The precipitation equation has nine terms accounting for 86% of the variance; the standard error is 415 mm (11% of the range of surface values). Plots of observed versus predicted temperature and precipitation indicate that the equations are reasonably structured within the limitations of the surface data set. Pollen spectra occasionally occur which seem to correspond with vegetation from warmer and wetter sites outside our surface data range. The equations predict excessively warm and wet conditions at these levels. Expansion of the surface data base would probably remedy this but samples are not available. Similarly, there seems to be some distortion of the record at the lower temperatures. Despite these limitations, we believe that trends are correctly described.

When applied to the fossil pollen stratigraphy at Taiquemó, the equations produce curves (Fig. 1) that can be fitted to the trends of temperature and precipitation between ~12,000 and 16,000 yr BP at Alerce. Only this portion of overlap in the two sets of data is shown to simplify the fit; the younger portions of the Taiquemó curves, represented by only 16 stratigraphical levels, lack a chronology and the detail shown by the 73 levels at Alerce. Accordingly, we have omitted data younger than 12,000 yr BP at Taiquemó in favour of the entire Alerce record.

Results indicate a mean January temperature of  $\sim 10$  °C between 14,120 and 31,200 yr BP. This followed a decrease from 12 °C around 43,000 yr ago. Minimum temperatures over the time span are  $\sim 4$  °C lower than present-day ones at Taiquemó. Precipitation is <1,000 mm from  $\sim 14,000$  until 21,900–26,600 yr BP; values are greatest before 31,200 and register a distinct rise to >4,000 mm around 43,000 yr BP. The range over which precipitation changes is >3,000 mm and is >1,500 above and below the modern mean of 2,600 mm. The long intervals with limited change seem unusual but are consistent with the minimal frequency variations shown in the pollen profiles at Taiquemó<sup>11</sup>.

Interstadial conditions at Taiquemó were clearly wetter and warmer around 43,000 yr BP. Precipitation has fluctuated less

but noticeably since then until ~14,000 yr BP, while changes in temperature are only  $\leq$ 1 °C. The minor increase in precipitation with no perceptible increase in temperature between 26,600 and 31,200 yr BP represents an apparent climatic event. The interval is also recognized in the pollen stratigraphy at Río Teguaco, 13.5 km directly south of Taiquemó, where it is  $^{14}$ C dated to between 25,500 ± 500 (QL-1017) and 30,000 ± 300 (QL-1019) yr BP. Drier and colder climate existed at Taiquemó during a stade that lasted until at least 14,000 yr ago. These climatic changes seem consistent with what is broadly known of glacier fluctuations in the region during the Llanquihue Glaciation  $^{11,13,14}$ .

Overall relationships can be drawn between the behaviour of the curves at Taiquemó and climatic conditions recognized from other data sources in the middle and higher latitudes of the Southern Hemisphere. The estimated 32,000-yr oxygen isotope

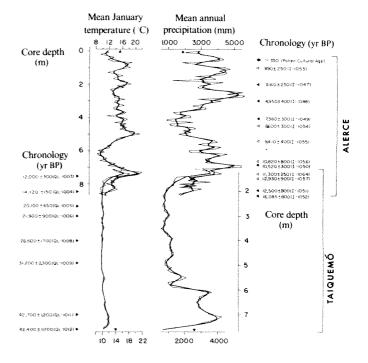

Fig. 1 Mean January temperature and mean annual precipitation at Alerce (upper scales) and Taiquemó (lower scales) for the past ~43,000 yr. Bold lines represent three-point moving averages of the data. Triangles on the temperature and precipitation scales indicate the modern means; <sup>14</sup>C ages are also indicated by triangles (closed ones relate to the cores whereas open ones for Alerce are from sites nearby that are stratigraphically correlated). Alerce and Taiquemó scales are offset slightly to align the curves.

stratigraphy for the Dome C ice core from east Antarctica4 indicates trends that are approximately parallel despite the degree of uncertainty in the Dome C chronology, which is taken from 14C ages of a marine core in the Indian Ocean. Major isotopic shifts indicate slightly ameliorated conditions before 25,000 yr BP, cold with decreased snow accumulation until ~16,000 yr BP (the time of the maximum advance of the West Antarctic Ice Sheet between 21,200 and 17,000 14C yr BP)15 and finally a warming trend that became stabilized close to 10,000 yr BP with minimal changes thereafter. Because of the uncertainty of the Dome C chronology, it is not possible to interpret certain changes in the stratigraphical record. This difficulty also applies to comparison of marine data with the Chilean data; however, estimated sea surface temperature profiles, derived from radiolarian assemblages in conjunction with oxygen isotope stratigraphy in marine sediments of the subAntarctic, do show the same trends as those at Taiquemó over what is interpreted to be the same time interval<sup>16</sup>

Pollen data from Tasmania<sup>5-8</sup> and New Zealand<sup>9,10</sup> in the zone of westerly winds (41-43 °S) are probably more relevant to the Taiquemó sequence of interstadial and stadial climates. At Blakes Opening in south-central Tasmania, a wetter and to some extent warmer interstade, when temperate rain forest developed, is <sup>14</sup>C dated earlier than 41,150 <sup>+1,45</sup><sub>-1,25</sub> -53,400 yr BP; later, wet sclerophyll forest succeeded in cooler and less humid conditions. The same climatic changes are apparent at Pulbeena and Mowbray Swamps in north-west Tasmania where grassy eucalyptus woodland or scrub in a cool, moist climate before 35,000 yr BP was followed by grassland associated with cold and lower humidity through the lateglacial. In northwestern South Island, New Zealand, the cold, relatively dry climate indicated by grassland continued until ~12,000 yr ago, except for an interstade characterized by shrubland with some spread of southern beech from ~26,000 until before 31,000 yr BP. Within the time limits set by the 14C chronology, these successive climatic events correspond remarkably with those apparent from the Chilean record over the same millennia.

We conclude that the trends of temperature and precipitation since ~43,000 yr BP, derived from the application of multivariate statistics to the pollen data at Taiquemó and Alerce, are generally representative of the Quaternary climates thus far established from some middle-latitude sites in the Southern Hemisphere. It should be possible to quantify further temperature and precipitation to demonstrate the degree of correspondence between land mass records through the last interglaciation. Fossil pollen records in this time range are available<sup>8,17</sup> but require quantification of the climatic variables from the pollen data.

### Palaeomagnetic excursions, aborted reversals and transitional fields

### Kenneth A. Hoffman\*

Research School of Earth Sciences, Australian National University, Camberra, ACT 2600, Australia

Recordings of palaeomagnetic excursions have revealed apparent field behaviour ranging from rather erratic directional mevements and loopings<sup>1-4</sup> to single, highly defined events<sup>5</sup> Excursions of the latter variety show what seems to be a rapid change in direction such that the path of the associated virtual geomagnetic poles (VGPs) is well constrained in longitude. Such behaviour is not unlike that observed at the onset of some recorded polarity transitions 7-9. Indeed, it has been suggested that excursions may occur during unsuccessful, or aborted, reversals2.5-7,10. We show here that available records of palaeomagnetic excursions, together with our present understanding of field behaviour associated with geomagnetic reversals, strongly support this hypothesis.

The ultimate question is: is it reasonable to consider at least some identifiable palaeomagnetic excursions to be records of aborted reversals and, therefore, relevant to our investigations of transitional field behaviour? If so, such data would provide a second major source of palaeomagnetic information to further our understanding of transitional field configurations and geomagnetic reversal.

It is first necessary to identify those palaeomagnetic recordings of claimed excursions which are the most likely to display accurately geomagnetic behaviour. As it is very important that the derived set of acceptable excursion records is not contaminated by spurious, inaccurate, or deceptive data, cautious and stringent criteria for acceptability must be imposed. For example, palaeomagnetic excursion data obtained from sediments will not be considered here, although they may include one or more reliable recordings (for example, ref. 4) Decause of the controversies and uncertainties surrounding many sediment-recorded excursions<sup>3,11</sup>. Similarly, excursion data obtained from sites at high latitude will not be considered. Exclusion of Icelandic data is particularly justified, given the relatively close proximity of the recording site to the geographical pole. The effects of secular variation at such high latitudes are known to be more pronounced and, hence tend to conceal systematic field behaviour related to excursion events. This may be the case with regard to Icelandic transition data12

Given the above arguments, to be considered acceptable a palaeomagnetic excursion record must: (1) be obtained from igneous rocks; (2) seem to be reliably determined, given the techniques used and results obtained; (3) contain a minimum of three successive data points (such as lava flows) associated with low-latitude (<45°) VGPs; (4) show that the intermediate directions were recorded during a clearly defined polarity state; and (5) be associated with a low or mid-latitude site.

Four excursion records satisfy the above criteria and, each is associated with a sequence of basalt lavas ranging from mid-Tertiary to Pleistocene. Table 1 lists the site description, age and relevant palaeomagnetic data for each. Note that all four of these acceptable excursion records show some longitudinal confinement of the low-latitude VGPs. As mentioned elsewhere, such behaviour is a common characteristic of palaeomagnetic recordings of Cenozoic polarity transitions

However, before comparing further these excursion data with those associated with successful field reversals, I shall briefly summarize our present knowledge regarding directional behaviour during field reversals.

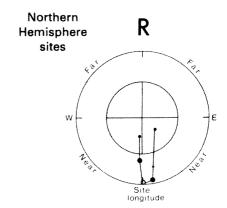

Recently much has been learned about the morphology of transition fields9. For example, comparison of palaeomagnetic records of the last reversal has shown the intermediate field to be predominantly non-dipolar 7,13,14. Moreover, VGP paths corresponding to this, as well as most other recorded Cenozoic polarity transitions, show a spatial dependence on the locality of the recording site 15. In particular, intermediate VGPs associated with reverse-to-normal  $(R \rightarrow N)$  transitions from sites in the Northern Hemisphere are found almost exclusively on the hemisphere centred about the respective site longitude 12.15, the so-called near side. Thus the non-dipolar component(s) controlling transition fields are axisymmetric and of low order<sup>12,15</sup>. However, our knowledge concerning this site dependence is incomplete. A more thorough understanding of transitional field geometries, as well as recognition of particular systematics associated with reversal in the core, require  $N \rightarrow R$ records from the Northern Hemisphere as well as records of both transition senses from the Southern Hemisphere<sup>12</sup>. At present the latter hardly exist9.

Two of the four acceptable excursion records correspond to events during normal polarity of the field and three of the recordings were obtained from sites at mid-southern latitudes. Hence, provided they are indeed representative of field behaviour during initiation of a reversal, these excursion records will greatly improve the existing polarity transition data set. Furthermore, provided the corresponding VGP behaviour is unambiguous, the combined successful/aborted reversal data may be sufficient to distinguish the predominant axisymmetric field geometry during transitions. Figure 1 shows the VGP data relative to site longitude, while taking into account the full polarity state of the field at the time of occurrence as well as the hemisphere of the recording site.

Note that the single record obtained from northern latitudes is associated with reverse polarity. Hence, this record serves to test further whether such field behaviour is the result of an unsuccessful reversal attempt. Comparison of the corresponding VGP path (Fig. 1, upper right) with existing  $R \rightarrow N$  transition data<sup>9</sup> strongly points to the affirmative. Indeed, this excursion path from Oahu, Hawaii is dramatically near sided with intermediate VGPs which closely straddle the site meridian. This finding, together with the weak relative remanence intensities associated with the excursion<sup>5</sup>, further justify the claim that aborted reversals exist in the palaeomagnetic record and, moreover, are

The remaining excursion data displayed in Fig. 1 correspond to records obtained from sites in the Southern Hemisphere. As with the Northern Hemisphere record, these three VGP paths are clearly found to be either near sided or far sided. In fact, it is

the single record corresponding to a reserve polarity excursion (Fig. 1, lower right) which is near sided while the two normal polarity excursions (Fig. 1, lower left) are far sided. Hence, all excursions which qualify as possible aborted reversals show intermediate VGP behaviour consistent with the finding in regard to transitional field geometries that non-dipole axisymmetric component(s) predominate. Moreover, the clear categorization of near-sided and far-sided paths by site locality and polarity state (during excursion) suggests that certain systema-

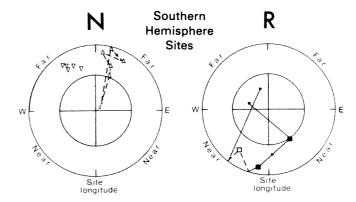

Fig. 1 Polar stereographic projections of VGPs from data sets listed in Table 1 and plotted with respect to site longitude. Each excursion is plotted separately depending on the hemisphere of the recording site and the full polarity state (N, normal; R, reverse) at the time of occurrence. Circles representing 45° latitude and the Equator are drawn in each case. Open and solid symbols (see also Table 1) represent Northern Hemisphere and Southern Hemisphere VGPs respectively. The Amsterdam Island data are shown without a path as a strict succession of flows was not presented in the literature<sup>6</sup>

<sup>†</sup> Width of meridional band containing all low-latitude VGPs.

<sup>‡</sup> Three of which are successive flows.

<sup>§</sup> VGPs calculated with respect to a location for Australia appropriate to the age of the sequence.

To be published elsewhere.

tics of the aborted reversal process exist. In fact, when these excursion data are combined with available detailed transition records9, a consistent set of VGP characteristics is obtained. Independent of the hemisphere in which the records were obtained, reverse polarity excursions and  $R \rightarrow N$  transitions are associated with near-sided VGP behaviour whereas normal polarity excursions and N -> R transitions are associated with far-sided VGP behaviour. These findings, listed by Hoffman and Fuller<sup>12</sup> as one possible regime, correspond to a predominantly quadrupolar  $(g_2^0)$  intermediate field geometry<sup>8</sup>

The finding that the VGP systematics depend on the sense of reversal supports the hypothesis that transitional fields are a result of the configurational characteristics of the reversal process in the core <sup>12–15</sup>. Moreover, these data are consistent with the idea that reversals have their origin in the Southern Hemisphere of the core. The hypothesis that a significant long-term standing (non-reversing) field exists during reversal attempts 16.17 is not supported, although a stationary field of short duration7 cannot be excluded.

Thus four records of palaeomagnetic excursions from low- to mid-latitude sites satisfy stringent criteria for reliability. Although few, these recordings display corresponding VGP behaviour which is constrained in longitude. Moreover, for each case, the path locality of the intermediate VGPs is unambiguously either near sided or far sided with respect to the longitude of the recording site. The single acceptable reverse polarity excursion from the Northern Hemisphere displays field behaviour consistent with that observed during R + N transitions also recorded at northern latitudes. These findings support the hypothesis that at least some geomagnetic excursions are aborted reversals and therefore the palaeofield variations derived from such records can be interpreted as transitional field behaviour. The intermediate VGP data (associated with the four acceptable excursion records), together with those from successful reversals, support the hypothesis that the controlling axisymmetric component of transition fields is quadrupolar. They also support the idea that the geomagnetic reversal process initiates in the Southern Hemisphere of the core. Why such an apparently symmetric entity as the Earth's outer core should be associated with an asymmetric reversal initiation process is debatable. The hypothesis of a long-term stationary, non-reversing field which controls the geometry during polarity transition attempts is not supported by these data. It remains to be seen whether additional palaeomagnetic records of either successful or aborted reversals will continue to support these conclusions.

I thank Drs M. W. McElhinny and P. L. McFadden for helpful discussions. This work was supported by NSF grant EAR-801879 (jointly awarded through the Geophysics Program and the US-Australia Cooperative Science Program) and travel grant from the Research School of Earth Sciences, The Australian National University; it was conducted during my sabbatical leave from California Polytechnic State University.

### Lower Proterozoic arc-microcontinent collisional tectonics in the western Churchill Province

John F. Lewry

Department of Geology, University of Regina, Regina, Saskatchewan, Canada S4S 0A2

Arguments favouring evolution of the 'Hudsonian' orogen of the Churchill Province through plate tectonic processes generally supported by recent work in Saskatchewan and Manitoba-11. Palaeomagnetic data do not preclude operation of the Wilson cycle in this region during the Lower Proterozoic 12-15, At present, however, subduction-related satures in the Churchill Province are unconvincingly documented. Even the Thompson Belt ('Nelson Front'), forming part of the postulated suture between the Superior Province craton and the western Churchill mobile belt (Fig. 1), is markedly oblique to major volcanoplutonic and other lithostructural belts of the western Churchill and is thus unlikely to be a simple collisional junction. Orogens formed at consuming plate margins are likely to incorporate pre-terminal, arc-related sutures, variably obscured by later events16. Previous proposals for location of such intraorogenic sutures within the western Churchill belt, predicated largely on geophysical evidence17, are unsupported by recent geological investigations5. However, on the basis of recent fieldwork, I now outline a strong geological case for intraorogenic collisional suturing and microplate interaction in south-east parts of the Churchill Province in Saskatchewan.

Six major lithotectonic elements can be distinguished (Fig. 1). (1) The Rottenstone-La Ronge Magmatic Belt, developed at the south-east margin of continental crustal terrain, represented by the Cree Lake Zone<sup>5</sup>, is a Hudsonian 'Cordilleran-type' arc massif<sup>6,10</sup>. Most of the belt comprises the plutonic core of the arc: subordinate calc-alkaline, arc-type (Watters, personal communication) volcanics-volcaniclastics are preserved mainly in south-east parts of the belt. There is markedly asymmetric distribution of plutonic rock types 10, with dominant quartz monzonite-granite-granodiorite in the north-west and calcalkaline quartz diorite-tonalite-granodiorite in the south-east.

(2) The eastern La Ronge domain, a metasedimentary belt up to 20 km wide, mostly comprises quartz-plagioclase-biotite psammites and semipelites interlayered with, and transitional to, calcareous hornblende/diopside psammites, hornblende gneisses and amphibolites 18,19. Pebbly psammites and immature polymictic conglomerates form thin layers up to major units in, and locally transitional to, both psammites and hornblende gneisses. These rocks are interpreted as volcanogenic proximal greywackes, volcaniclastic-epiclastic sediments with minor lavas, and submarine fan deposits, derived from the Rottenstone-La Ronge arc. Both arc volcanics and derived sediments are stratigraphically overlain by locally conglomeratic arkoses preserved within an overturned disrupted synform on the western margin of the sedimentary belt.

The domain is affected by at least two deformation events which produced coplanar, north-east-trending isoclinal folds, foliation, limb-sliding and thrust stacking. These structures are deformed by open folding about north-trending axial surfaces. Strain indicators suggest extreme flattening normal to early foliation and fold axial surfaces, with very high extensional strains in the downdip direction.

On the basis of location, lithelogy and deformation, the eastern La Ronge domain is interpreted as the severely telescoped remnants of a forearc basin.

(3) Most of the Glennie Lake domain comprises early quartz dioritic-granodioritic orthogneisses and later foliated to undeformed dioritic to granitic plutons. Subordinate supracrustals occupy narrow arcuate belts within the orthogneisses: in the north-west they are in part continuous with, and similar to, supracrustals of the eastern La Ronge domain; elsewhere they include more abundant volcanics.

The domain has distinctive structural character. Early orthogneisses and supracrustals possess initially flat-lying gneissic foliation, isoclinal folding and lineation resulting from at least two deformation events. In the north-west, major recumbent folds can be correlated with more steeply overturned  $D_2$  isoclines of the Eastern La Ronge domain. These nappes are refolded by large wavelength, open to tight, north-trending  $D_3$ , and north-east-trending  $D_4$  folds, producing type 1 interference patterns. Differences in lithological character and structural succession in adjacent supracrustal zones  $^{20}$  may result from juxtaposition of autochthonous and allochthonous elements.

Most documented thermotectonic and plutonic events in the Glennie Lake domain are probably Hudsonian: limited Rb/Sr whole-rock dating (K. Bell and J. Blenkinsop, personal communication) has to date yielded no pre-Hudsonian ages. Nonetheless, lithostructural character and the nature of domain boundaries indicate that the domain possesses fundamentally different basic crustal structure and evolution compared with adjacent domains.

The south-west part of the La Ronge-Glennie Lake domain junction is defined by the 2-4 km wide Stanley Shear Zone<sup>18</sup> which incorporates submylonitic and blastomylonitic gneisses interpreted, on structural and metamorphic evidence, to have developed early in local thermotectonism. To the north-east, this early 'straight belt' disappears and the Stanley Zone is marked only by late dextral strike-slip faults, across which broad

continuity of lithology and structural trends occur. Even here, however, the domain junction is marked by major changes in fold style and attitude.

(4) South of Reindeer Lake, the Tabbernor Zone is a narrow 'straight belt' with a complex history dating from early- and possibly pre-Hudsonian time. It includes blastomylonitic gneisses formed early in Hudsonian thermotectonism<sup>21,22</sup>, tightly appressed northerly-trending folds and syn- to post-metamorphic faults. The zone is marked by a pronounced metamorphic gradient<sup>21,23</sup>. The southern part of the zone was thus a fundamental crustal dislocation active throughout Hudsonian orogeny.

To the north, the Tabbernor Zone changes abruptly in character and documented history as it extends across the Rottenstone–La Ronge belt, marked most obviously by splaying of the shear zone into a broader, diffuse set of fractures. The latter are associated with late Hudsonian open northerly folds in the La Ronge domain but these disappear farther north and the Tabbernor system is thereafter characterized only by brittle faults with sinistral strike-slip displacement. All early Hudsonian phenomena disappear as the Tabbernor Zone leaves the Glennie Lake–Kisseynew terrain.

(5) The Kisseynew domain mostly comprises highly migmatized, proximal to distal volcanogenic metagreywacke turbidites, subordinate metavolcanics and arkoses<sup>7,24</sup>. Interdigitating facies relations with supracrustals of the La Ronge-Lynn Lake and Flin Flon-Snow Lake volcanoplutonic arcs are well documented and the 'Kisseynew Gneisses' are generally interpreted as being deposited in part contemporaneously with arc development. Original continuity between the northern Kisseynew terrain and the eastern La Ronge forearc seems certain.

Most granitoids of the Kisseynew domain are locally derived anatectites. Major Hudsonian plutons are uncommon, except adjacent to the La Ronge and Flin Flon belts. Older 'basement' is recorded only immediately east of the Tabbernor Zone, in the south-west part of the domain: the Sahli Granite is dated at  $2,430\pm30$  Myr (Rb/Sr whole rock isochron)<sup>25</sup> and volcanics and granitic rocks in the Hanson Lake area at 2,521 and  $2,446\pm16$  Myr (Rb/Sr whole rock isochrons)<sup>26</sup>. Rocks of the latter area are akin to those in adjacent parts of the Glennie Lake domain and provide tenuous geochronological indication of possibly extensive older continental basement in the latter.

(6) The Flin Flon domain (and its extension, the Snow Lake belt of Manitoba) is a well documented Lower Proterozoic arc complex<sup>27-29</sup> similar in most respects to the Rottenstone-La Ronge Magmatic Belt. Age data indicate that the two arcs are essentially coeval but suggest the Flin Flon arc could be slightly younger<sup>30</sup>.

The Glennie Lake domain has previously been interpreted, speculatively, as incorporating pre-Hudsonian continental crust<sup>6,11,18</sup>. While this is unconfirmed by radiometric data the domain possesses distinctive lithostructural style and is bounded largely by major tectonic discontinuities. Metamorphic data strongly emphasize domainal contrasts and support interpretation of the Tabbernor Zone as a fundamental crustal feature. Interpretation of the Glennie Lake domain as possessing radically different pre-Hudsonian crustal character, relative to adjacent domains, provides a possible explanation of regional geology and gross structural geometry, and accords with a general model for Hudsonian evolution in the southeastern Saskatchewan–Manitoba Shield.

It is thus argued that in early- to mid-Hudsonian time the Glennie Lake domain formed a microcontinental block within a dominantly oceanic lithospheric plate which was subducting beneath the Rottenstone–La Ronge arc along a consuming plate margin located south-east of the eastern la Ronge–northern Kisseynew terrains (Fig. 2a). This resulted in collision of the Glennie Lake block with the eastern La Ronge forearc and ensuing arc–microcontinent suture (Fig. 2b). The collision produced extreme telescoping of the forearc prism, locally leading to almost complete squeezing out, at the present erosion

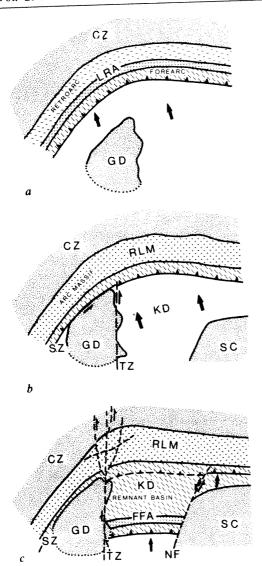

Fig. 2 Possible tectonic evolution of the south-east Churchill Province in Saskatchewan and Manitoba. a,  $(\sim 1.950-$ 1,900 Myr?): early Hudsonian development of subduction zone and La Ronge-Lynn Lake volcanic arc marginal to Cree Lake continental margin. The Glennie Lake domain is an 'outboard' microcontinent within a predominantly oceanic subducting plate. b, (~1,900-1,870 Myr?): collision of Glennie Lake domain with eastern La Ronge forearc and initial telescoping of the forearc prism. Uncoupling occurs between the impeded Glennie Lake microplate and still subducting Kisseynew microplate with initiation of the southern Tabbernor Zone. The arc is uplifted and stripped to form a major Cordilleran-type arc massif, the Rottenstone-La Ronge Magmatic Belt. The Flin Flon-Snow Lake arc may be initiated by migration of subduction site southwards between the Tabbernor and Thompson 'transforms' or may already have been active in the outboard part of the southern plate.  $c_1 (\sim 1,860 \text{ Myr?})$ : the Glennie Lake domain is sutured to the arc massif with immense telescoping of the forearc and possible transcurrent reactivation along the suture. Subduction north of the Kisseynew domain has ceased and the suture buried beneath sediment influx. The Kisseynew subplate becomes an interarc remnant basin receiving sediments both from north and south. Differential movements propagate the Tabbernor Zone northwards as a splaying wrench system. The Thompson Belt forms another transcurrent/transform junction, to the east of which incoming of the Superior continent leads to terminal collision along the northern part of the Nelson Front, followed by general compression, late folding, continuing propagation and reactivation of major fractures. Assigned dates are speculative, based on limited radiometric data. CZ, Cree Lake Zone; GD, Glennie Lake Domain; SC, Superior Craton; LRA, La Ronge-Lynn Lake Arc; FFA, Flin Flon-Snow Lake Arc; RLM, Rottenstone-La Ronge Magmatic Belt; KD, Kisseynew Domain; SZ, Stanley Zone; TZ, Tabbernor Zone; NF, Nelson Front (Thompson Belt).

level, of forearc sediments between the arc massif and microcontinent. Deformation and indicated bulk strain in the forearc belt are consistent with this interpretation. Recumbent fold/thrust sheets were driven southeastwards out of the forearc across the advancing microcontinent. In part, such nappes may include thrust slices from the leading edge of the microcontinent. The Stanley Shear Zone is thought to represent, not the actual collision suture, which is presumably overridden, but the main sole zone of detachment of allochthonous sheets moving over the Glennie Lake block. Farther north this detachment zone is folded and plunges beneath the allochthon.

Further deformation in the Glennie Lake domain, accompanying final collision stages (and possibly related also to new or continuing subduction to the east or south) resulted in major refolding of autochthonous basement and allochthonous cover, accompanied and outlasted by plutonism. Reactivation along the suture zone produced later faulting which extended into the overriding allochthon, thus generating the presently exposed north-east part of the Stanley fault system.

The Tabbernor Zone is interpreted as a transform junction initiated between the Glennie Lake microcontinent and the Kisseynew subplate (which may be underlain by predominantly oceanic lithosphere). Uncoupling along this zone is thought to have accompanied locking up of the Glennie Lake block in relation to still subducting lithosphere underlying the Kisseynew domain (Fig. 2c). Though the Tabbernor Zone generally conforms to the Glennie Lake domain junction it seems that prominences were detached as fragments within the dominantly oceanic subplate, as, for example, the Hanson Lake block.

The Kisseynew basin was filled with detritus from the La Ronge-Lynn Lake and Flin Flon ares, which may have been active simultaneously for a time: alternatively, the Flin Flon arc may be younger and result from rapid migration, or jump, of the subduction site along the transform junction. Resolution of these alternatives awaits more refined stratigraphic mapping and radiometric dating. The subduction zone related to the eastern part of the La Ronge-Lynn Lake arc is thought to be buried beneath Kisseynew basinal sediments.

The Flin Flon-Snow Lake arc is bounded by the Tabbernor Zone to the west and the Thompson Belt to the east: the latter is interpreted as another major transform, or transcurrent, junction between the Kisseynew subplate/remnant ocean basin and Superior continental craton. Northerly subduction beneath the arc is invoked to explain high grade metamorphism of the Kisseynew terrain, as compared with the southern Glennie Lake domain and Superior craton.

Stresses induced in the already crystalline Rottenstone-La Ronge arc massif and Cree Lake Zone, due to differential activity of segments of the subducting plate, are postulated to have caused northwards propagation of the Tabbernor Zone across the underthrust continental plate as a splaying wrench system. Further propagation and reactivation accompanied late-Hudsonian terminal collision and overall compression, producing sinistral displacements along the Tabbernor Zone and reactivation of other major discontinuities such as the Stanley Zone.

The proposed model accounts for hitherto unexplained differences in character of northern and southern parts of the Tabbernor Zone and its oblique orientation relative to other elements of the western Churchill Province. It provides a viable explanation of the 'abberrant' orientation of the Thompson Belt in plate tectonic modelling of the Hudsonian orogen.

#### Volcanic components in pelitic sediments

#### Paul H. Nadeau\* & Robert C. Reynolds Jr

Department of Earth Sciences, Dartmouth College, Hanover, New Hampshire 03755, USA

The origin of the clay minerals present in pelitic sediments has been widely debated. Weaver suggests that illite and interstratified illite/smectite (I/S) dominate. The association of illite with marine sediments<sup>2</sup> and the proposal<sup>3,4</sup> that illite forms from smectite (an expandable clay mineral sometimes referred to as montmorillonite) in the marine environment has also been discussed. Weaver<sup>5</sup> argues for a continental origin of illite, produced by weathering of K-feldspar. Others 6-9 have shown that smectite and I/S (20-50% illite) are converted to I/S of higher illite content (60-80%) in pelitic sediments by low-grade metamorphism. Per cent illite will always refer to the per cent illite in I/S. The designation should not be confused with the content of discrete illite or mica commonly present in these sediments. Here we present clay mineral and K-Ar data for Cretaceous marine shales from the Western Interior of North America demonstrating a volcanic origin for much of these sediments. This observation is correlated with eustatic sea-level rise, increased volcanic activity, sedimentary preservation of organic matter, and incorporated into a petrogenetic/tectonic model for pelitic sediments.

It has been shown 8-10 that Cretaceous marine sediments from the Western Interior of North America are primarily composed of random I/S11. In some areas, the clay mineral assemblages of these sediments have been converted to ordered I/S<sup>8,9</sup> and illite by low-grade metamorphism. Unpublished X-ray diffraction data of contact metamorphic Cretaceous clay mineral assemblages in the Spanish Peaks area, Colorado, clearly demonstrates that the I/S is converted to 100% illite. Fine-grained, vitreous, volcanic debris is generally accepted as the source of the smectite clay<sup>1,12</sup>. The presence and resulting mineralogy of numerous bentonites13 associated with these sediments supports this interpretation. I/S clay mineral data from 77 bentoniteshale sample pairs in the Cretaceous Mancos shale are shown in Fig. 1. Excellent agreement between the nature of interstratification of the sample pairs is indicated. Although the bentonites order before the shales, the per cent illite is generally higher in the shales, particularly for those sample pairs of random interstratification (Fig. 1). Schultz<sup>10</sup> has noted a similar discrepancy and proposed that this greater amount of illite in shales compared with bentonites may be related to longer marine residence times of volcanic debris and consequent alteration to random I/S in the resulting shales. High sedimentation rates of volcanic debris, resulting in the formation of

Table 1 K-Ar age determinations of clay size fractions from Cretaceous marine shales

Sample	Potassium-bearing clay mineral	Age (Myr)
MS921	Randomly interstratified illite/	98.3±4
MS86	smectite (I/S), 50% illite Discrete illite	(Upper Cretaceous) 2.3 ± 8 (Triassic)

distinct bentonite beds, have a much shorter marine residence time and are therefore essentially smectitic. Consequently, bentonite-clay alteration occurs primarily below the sedimentwater interface, and may explain the very low illite content of I/S in bentonites. We agree with this interpretation. However the similarity in clay mineralogy of non-marine and marine Cretaceous pelitic units may indicate a continental role in the formation of random I/S from volcanic debris (L. G. Schultz, personal communication). This point is important because the location of clay potassium adsorption, and consequent formation of illite, has major implications with regard to the chemical cycle and distribution of potassium in the lithosphere and hydrosphere. For this discussion, we contend that despite the discrepancy in illite contents of I/S, the gross similarity of the clay mineralogy of Cretaceous shales and bentonites, particularly with regard to the nature of interstratification, suggest a common origin, that is, the result of alteration of volcanic debris.

K-Ar investigations of pelitic sediments, which are primarily concerned with the dating of illite, the major potassium-bearing phase, have produced complex results14 that are partly due to the mixing of detrital illite derived from older lithologies and younger metamorphic illite<sup>15,16</sup>. Similarly, K-Ar interpretation of the Cretaceous shales is complicated by the presence of minor amounts of discrete illite in almost all the clay size fractions of the samples. However, a few shales were found to have clay size fractions composed of either random I/S or pure discrete illite. K-Ar determination of these samples (Table 1) indicate that the discrete illite (MS86) is probably detritus from an older source (213 Myr), that is, pre-Cretaceous, whereas the random I/S (MS921) yields approximately the correct stratigraphic age (98 Myr). Additional evidence is provided by the K-Ar investigation of Hoffman<sup>17</sup> on Missouri River sediments in which Cretaceous shales are the major stratigraphic units in the drainage basin. In this study, clay minerals from 11 sediment samples, essentially random I/S, yielded ages of 79-125 Myr averaging ~100 Myr. Bentonites, on the other hand, often contain no detrital sedimentary components. If the original smectite in bentonites is converted to ordered I/S, there is little doubt that the measured age records potassium fixation and

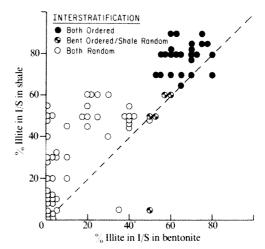

Fig. 1 Relationship between percentage illite in interstratified illite/smectite (I/S) from bentonite-shale sample (equivalents line (broken) is shown for comparison).

<sup>\*</sup> Present address: The Anschutz Corporation, 555 17th Street, Denver, Colorado 80202, USA

consequent illite formation during burial or contact metamorphism 16. Five samples of such bentonite materials were dated by K-Ar methods, and produced ages between 62 and 40 Myr (ref. 18). The clay from shale that has the correct stratigraphic age (98.3 Myr) could be produced by a mixture of discrete illite and ordered I/S, however, no trace of either discrete illite or ordered I/S was resolved by X-ray diffraction. A simple calculation shows that sufficient 200-Myr material is needed to increase a 60-Myr age to 100 Myr producing a mixture in which discrete illite would have been clearly resolved in the diffraction pattern. We therefore conclude that the 98.3-Myr random I/S is a mineral phase whose potassium content was fixed at or near the time of Cretaceous sedimentation, hence supporting the contention that random I/S represents first-cycle sedimentary material resulting from the alteration of volcanic debris. Hoffman<sup>17</sup> drew similar conclusions from his age data.

The Cretaceous is an unusual period in several respects. The proliferation of epicontinental marine sediments due to a high stand of eustatic sea level during this period produced marine transgressive sedimentary sequences on almost all the continents19,20, including the invasion of marine depositional environments into the Western Interior of North America. Gilluly21 shows the difficulty in providing a detrital source area for the Cretaceous marine sediments of North America (volume =  $4 \times 10^6 \text{ km}^3$ ). Based on particle size and quantitative clay mineral analyses of the Cretaceous Pierre shales, I/S represents ~38% of the total sediment<sup>22</sup>. From a comparative study of coarser size fractions of the Pierre shales with those of bentonites Jones<sup>23</sup> estimates that  $\sim 40\%$  of these sediments are the result of pelagic deposition of aeolian transported volcanic debris. Therefore, the data indicate that approximately onethird to one-half of these sediments are of volcanic origin, possibly explaining the difficulty in reconciling their source from reworked older rocks. The influx of volcanic material into the Cretaceous marine environment was episodic, and at times completely dominated the sedimentation as evidenced by the presence of numerous bentonites. This form of sedimentation is characterized by relatively uniform sediment accumulation over much of the basin and is much different from that of fluvial deltaic systems that localize sediment in more restricted depositional environments. Petrologically, the Cretaceous shales have many features in common with black shales elsewhere. The depositional environments resulting in the formation of black shales are of great interest because of their association with hydrocarbon and some types of metallic ore deposits. Factors important in their formation are organic productivity, sedimentation rate, and rate of oxidation of organic matter before burial<sup>24,25</sup>. The volcanic-sedimentary episode may have had other geochemical consequences, such as the influx of chemical elements into the atmosphere and oceans from volcanic ash and gases. These factors may provide a conducive environment for the formation of black shales. Organic-rich pelagic sediments were preserved globally in various marine environments during the Cretaceous<sup>26,27</sup>. These 'anoxic events' have been correlated with the rise in eustatic level, increases in organic production and changes in global climate. Scholle and Arthur<sup>28</sup> have shown that the <sup>13</sup>C isotopic composition of Cretaceous carbonates increases from 120 to 80 Myr, reaching a maximum at 108 Myr. This increase in <sup>13</sup>C is correlated with the increased preservation of organic matter in these sediments. Other studies<sup>29,30</sup> have shown a dramatic 3-4-fold increase in the rate of seafloor spreading (up to 18 cm yr<sup>-1</sup>) during the mid-Cretaceous (110-85 Myr), and that there is a direct relationship between the rate of spreading and eustatic sea level. Kauffman<sup>31</sup> has noted a correlation between emplacement of calc-alkaline batholiths and bentonite frequency in marine sediments, suggesting a link with tectonic activity. McBirney<sup>32</sup> observed a relationship between marine transgressions and episode volcanic activity which tends to be synchronous over a broad region of the Earth. All the evidence suggests that these dynamic Earth processes are related. The record of high eustatic sea level would correspond to periods of higher volcanic activity, the debris from which

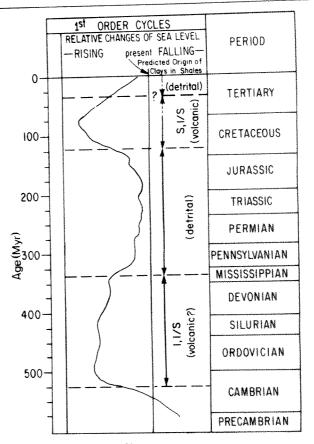

Fig. 2 Eustatic sea level<sup>20</sup> and clay petrology of pelitic sediments (mainly after ref. 1) throughout the Phanerozoic. I, illite; I/S, interstratified illite/smectite; S, smectite.

accumulates in the greatly expanded marine environment, readily altering to smectite and random I/S.

This discussion may be relevant to the origin of the bulk of clay minerals preserved in pelitic sediments. Are there any analogues to this form of sedimentation proposed for the Cretaceous? Some cases of the lower to mid-Palaeozoic systems of eastern North America are good candidates, given the proliferation of marine sedimentation, the widespread occurrence of Ordovician and Devonian bentonites, and the formation of black shales. In Weaver's classic work on the clay petrology of sediments, he notes that the dominant clay mineral present in pre-Upper Mississippian sediments is illite and I/S. Here again a discrepancy exists between the clay mineralogy of Palaeozoic bentonites, which are I/S, 80-90% illite, and shales which contain I/S that is generally 90% illite, and illite. In the Cretaceous sediments, I/S in the shales have a higher illite content than do the bentonites, and should this lag in illite content continue through higher grades of burial metamorphism, the I/S of shales would be expected to convert the 100% illite before the I/S of the bentonites. Given the relationship of eustatic sea level and volcanic activity, inspection of Fig. 2 predicts that much of the illite and I/S of these sediments may represent the accumulation of volcanic debris, originally in the orm of nearly pure smectite and random I/S, later modified by netamorphic conversion of smectite to illite. Periods of low eustatic sea level would be predicted to have a lower overall volcanic influx, allowing the reworked detrital influx to dominate. The abundance of pelitic sedimentary and metamorphic rocks, which make up more than half of the sedimentary record<sup>34</sup> in continental source areas, combined with the stability of phyllosilicates in aqueous systems are in part responsible for their presence in detrital clay mineral assemblages. Therefore, incorporation of older, volcanically derived clay into later depositional environments is a common occurrence. The Clay mineral assemblages of the Upper Palaeozoic and Lower to Middle Mesozoic<sup>1,2</sup>, as well as Recent marine sediments<sup>33</sup>, are in fact, highly variable in composition and lack

the uniformity of the lower to mid-Palaeozoic and most of the Cretaceous.

We have tried to rationalize many different facts and hypotheses for the Cretaceous sedimentation in North America. A major marine transgression was accompanied perhaps by increased volcanic activity at the subduction zones. Clay mineral and K-Ar data from Cretaceous shales suggest that the smectite and I/S which are major components in these sediments are derived primarily from volcanic debris. Thus one model exists that explains the aqueous environment for the accumulation of a sedimentary record, and the volcanic sources to fill it. Illite, I/S and smectite are the dominant clay minerals in pelitic sediments. The similarity between clay mineral assemblages of Lower to Middle Palaeozoic marine shales with the inferred mineralogy of Cretaceous marine shales after deep and prolonged burial suggests that the Cretaceous model described above may be general, and that the derivation of smectite and random I/S from volcanic debris and its later metamorphic conversion to ordered I/S and illite is a major reaction sequence affecting the clay petrology of pelitic sediments.

We thank Leonard Schultz, Harry Tourtelot, Hugh Jenkyns and Richard Pollastro for reviewing the manuscript; and James Aronson and Charles Drake for helpful discussions.

#### Sinian microfossils from south-west China

#### Wang Fuxing

Chengdu Research Institute of Geology and Mineral Resources, Chengdu City 610081, Sichuan, China

The microfossil assemblages described here are preserved in cherts from the Yunnan Province, south-west China. They are the first chert-facies microfossils to be discovered in the Wangjiawan and Meishucun stratigraphical sequences which are regarded by the International Cambrian/Precambrian Boundary Working Group1 as possible 'candidates' for the stratotype section of the Cambrian/Precambrian boundary.

The rock samples in which the microfossils were found were collected from the middle member of the Dengying Formation and from the lower member of the Meishucun Formation of the Sinian 'system' the Wangjiawan and Meishucun sections (Fig. 1). The carbonaceous rocks of the upper member of the Meishucun Formation at both sections (W. and M.) have been dated to  $603 \pm 31$  Myr and  $612 \pm 36$  Myr respectively (by Rb-Sr isochron dating where  $\lambda^{87}$ Rb is 0.142 yr<sup>-1</sup>)<sup>1</sup>. The fossiliferous area of the Meishucun Formation in the Wangjiawan section is more than 60 m below the oldest trilobite-bearing beds of the Lower Cambrian and about 15-20 m above the lowest occurrence of small shelly fossils. The stratigraphical position in the Meishucun section is more than 50 m below the oldest trilobite-bearing beds. The fossiliferous bed of the Dengying Formation of the Wangjiawan section is more than 100 m below the lowest beds containing small shelly fossils. The fossiliferous rocks consist of non-stromatolitic chert laminae or lensed bodies (nodules) which form intercalated beds in dolomite or dolomitic fine-grain sandstone.

The type of microfossil preserved in the cherts of the Wangjiawan section is the same as that previously reported for Precambrian deposits; however, the microfossils from the cherts of the Meishucun section are strongly mineralized, light in colour and partially or totally lacking in organic matter, so that they can only be considered as fossils on the basis of their apparent biological nature. Secondary silification may be a good process for preserving microfossils originally mineralized after

The Dengying and Meishucun microfossil assemblages are morphologically of three forms-spheroids, trichomes and sheath-like filaments. Most of the coccoids and filamentous forms are well preserved. Although most of the fossils are degraded forms and lack detailed structure, their morphology, size range and the cell structures occurring randomly in some of the samples enable their classification either as a previously described Precambrian taxon or as a new genus or species.

Among the coccoids, the colonies shown in Fig. 2f are assigned to Clonophycus Oehler<sup>2</sup>, which have been compared with large cells of eukaryotic green or red algae; those in Fig. 2e, g are assigned to Myxococcoides kingii Muir<sup>3</sup>; and the samples shown in Fig. 2n may be a new taxon of non-ensheathed colonies composed of unicells which occur in individual spheroids, in pairs or in planar tetrads, and are 7-22 µm in diameter (commonly 11-16 µm), with a psilate surface texture, but no sheath or organic matrix. Both the known taxa can be compared with members of the Recent Chroococcaceae. Samples of solitary unicells (Fig. 2a-c) are assigned to Myxo-

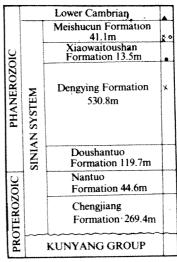

Fig. 1 Stratigraphy of the Sinian System in Yunnan Province, China, showing the occurrence of fossiliferous chert samples from the Wangjiawan section (X), the Meishucun section (O), and the oldest trilobite bed (A) and lowest bed containing small shelly fossils ( ) in Wangjiawan section.

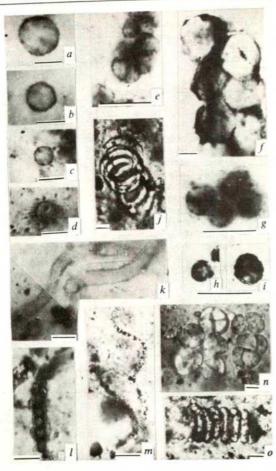

Fig. 2 Optical photomicrographs of the Sinian fossils discovered in chert thin sections from the Meishucun Formation (a-e, g-i, k) and the Dengying Formation (f) of the Wangjiawan section, and from the Meishucun Formation of the Meishucun section (j, l-o). Scale bar,  $10~\mu m$ .

coccoides grandis Horodyski & Donaldson<sup>4</sup>. Spheroidal envelopes (or round flattened membranes) (Fig. 2h, i), which closely resemble acritarcha fossils obtained by simple palynological methods from Precambrian sediments, are of the taxum *Protosphaeridium* Timofeev<sup>5</sup>. Several coccoidal unicells with radial setaceous spines (Fig. 2d) were discovered in the cherts of the Meishucun Formation from the Wangjiawan section; they resemble members of acritarcha *Baltisphaeridium* discovered in Russian Cambrian sediments by macerating rock<sup>6</sup>, and are 6.5–7 μm in diameter, with spines <0.5 μm wide and 2.5–5 μm long.

In some thin sections of chert from the Meishucun Formation of the Wangjiawan section only one kind of non-septate filament (Fig. 2k) has been discovered which has been assigned to Eomycetopsis robusta Schopf emend Knoll & Golubic<sup>7</sup>. This taxum includes structures resembling the empty sheath of cyanophitic or bacterial trichomes. Other sections from the same formation contain extensively degraded non-septate filaments of this taxum (Fig. 2m) together with an abundance of several other kinds of filament. Those shown in Fig. 3h, i are of the species Cyanonema inflatum Oehler<sup>2</sup>; comparable with the recently discovered member of Oscillatoriaceae; the coiled filaments shown in Fig. 2j, o are assigned to the Obruchevella parva Reitlinger<sup>8</sup> and comparable with recently discovered cyanophitic blue-green alga Spirulina. The sample illustrated in Figs 2l and 3a-g, j may be a new taxon.

The filaments shown in Fig. 3f, g appear to be unbranched, uniseriate, septate and multicellular and resemble Cyanonema inflatum except for the occurrence of a thin sheath and some larger cells that may be heterocysts (?) typical of the Nostocaceae. The specimens shown in Fig. 3e seem to be degraded

trichomes of uniseriate, septate, multicellular filamentous algae, although the filaments have indistinct outlines; the septate filaments can also be seen in the well preserved larger cells (which may be heterocysts) distributed along the filament. The trichomes are  $\sim 3-4~\mu m$  in diameter, and the larger cells 4–5  $\mu m$  wide and 4.5–6.5  $\mu m$  long; each of the larger cells contains a black body, 1–2  $\mu m$  in diameter, irregular or oval in shape and comprised of degraded cellular matter. The specimens are similar to members of the genus  $Veteronostocale^9$ , which has been compared with recently found Nostocaceae; however, they are unnamed here because of their poor state of preservation.

The larger filaments dicovered are shown in Fig. 3a-d, j; all resemble recently discovered members of Oscillatoriaceae, being unbranched, uniseriate, septate and multicellular or nonseptate tubular, disk-like trichomes with a distinct sheath. Figure 3a shows an ensheathed trichome; such trichomes occur as a coiled filament 26-30 µm in diameter, as a round coiled body 250 μm in diameter, or as disk-like medial cells, 3-8 μm long and 26-28 µm wide. The samples may represent fragments of a larger member of the Obruchevella, or a new taxon not yet described, and are tentatively named here Circulinema jinningense gen. et sp. nov. on the basis of their preserved state. The coiled filaments shown in Fig. 3b-d resemble C. jinningense except for their lack of internal cells; they occur in non-septate form are 19-21 µm in diameter and coil to give bodies 73-140 µm in diameter; this type of coiled filament may represent the empty sheath of C. jinningense or the degraded form of the latter which have few or no internal cells because of degradation. Figure 3j shows a fragment of a larger member of the Oscillatoriaceae, 27-28 µm in diameter, with a distinct sheath and disk-like medial cells.

The Sinian microfossils described here are of interest in Precambrian microbial study because: (1) although other Pre-

Fig. 3 Optical photomicrographs of the Sinian fossils discovered in chert thin sections from the Meishucun Formation of the Meishucun section. Scale bar, 10 μm.

cambrian microfossils have been described in China, they are mainly acritarcha fossils macerated from non-chert rock samples; few microfossils from cherts of both stromatolitic and non-stromatolitic types have been described10. The assemblages described here are apparently the best Sinian assemblages from south-west China reported to date. (2) The Sinian assemblages occur near the Cambrian/Precambrian boundary, and the abundance of the wider filaments and some stratigraphically definite taxa, such as the Obruchevella parva reported only from sediments near the Upper Proterozoic/Lower Phanerozoic boundary8, may allow assignment of a late Proterozoic age for the sediments. (3) Although the small and ensheathed colonial unicells and filamentous fossils dominate in the described formations and suggest cyanophytic affinity with Chroococcaceae, Oscillatoriaceae and Nostocaceae, the large coccoids are larger than most of the cyanophytic taxa and may be eukaryotic like the members of Chlorophyceae or Rhodophyceae discovered in stromatolitic cherts. This suggests that the stromatolite-building algae are taxonomically similar to the dominant benthic algae inhabiting the supra-, sub- and intertidal late Precambrian environment, and it is of interest to know where and how these microorganisms build the stromatolites. (4) The better preservation of the mineralized microfossils in cherts of the Meishucun Formation in the Meishucun section may indicate the importance of secondary mineralization as a means of preservation and that this kind of microfossil is probably filled by collophanite before replacement by apatite.

I thank Mr Zhang Shishan for help with the field work, Professor Chu Haojan, Ding Lianfang, Drs S. M. Awramik, M. D. Muir, C. V. Mendelson, J. W. Schopf, Ding Lianfang and J. H. Oehler, for advice and help.

#### Tree remains in a North York Moors peat profile

#### I. G. Simmons

Department of Geography, University of Durham, Science Laboratories, South Road, Durham DH1 3LE, UK

#### J. B. Innes

Archaeological Survey of Merseyside, Merseyside County Museums, William Brown Street, Liverpool L3 8EN, UK

It has been postulated1,2 that in the southern Pennines above 350-400 m, burning of the vegetation during Mesolithic time prevented the growth of trees, and that this continued during Neolithic time, although it was suggested that some recolonization of forest took place when agriculture made it possible to diminish the impact of hunters on wild animal food resources and on these uplands. Here we present analogous evidence but come to a slightly different conclusion which may be due to regional differences in prehistoric settlement. Peat profiles such as we describe here are uncommon in the region and so the phenomena may have been spatially restricted.

Table 1 Stratigraphical units at Bonfield Gill Head

***************************************			
Unit letter*	Horizons occupied (cm)	Peat type	Wood and macroscopic charcoal contents*
1	0-20	Sphagnum peat	No charcoal
k	20-40	Well humified peat with some remains of Eriophorum	No charcoal above 41 cm, Betula stump at 38-41 cm
j	40-52	Less well humified	
	(Ulmus	Eriophorum peat,	
	decline	some Ericaceae	
	at 41 cm)	twigs	
i	52-54	Wood layer and amorphous peat	Betula wood: bark, branches and twigs
h	54–58	Charcoal and amorphous peat	Large pieces of charcoal
g	58-70	Eriophorum peat	
g f	70-77	Well humified peat and wood	Small wood pieces (up to 10×5 cm)
e	77–81	Peat and charcoal	Charcoal mostly macroscopic but 'soot' also present
d	81-90	Wood fragments and peat	Betula fragments
c	90-97	Minero-organic amorphous peat	
b	97-105	Sand + wood and bark fragments	Tiny pieces of woody material
a	105 →	White clay	*

See Fig. 1.

We examined the peat profile from the head of Bonfield Gill (grid ref. SE 598958: 346m altitude) which runs east-west across Bilsdale Moor in an area of patchy blanket peat which has eroded in places to reveal stumps and trunks of sub-fossil trees (Betula and Quercus spp.) of a substantial size; the remnants of forest rather than scrub are suggested by trunks 0.6-1.0 m in diameter with roots spreading a further 1.25 m to each side. Investigation of the basal 100 cm of a typical profile of 2-m depth of organic material reveals several stratigraphical units (Table 1 and Fig. 1). The key elements in the stratigraphy are the presence of wood in several layers and the occurrence of charcoal and 'soot' (microscopic charcoal fragments) particles throughout. An estimate of the frequency of the microscopic particles at different horizons is given in Fig. 2. Macroscopic charcoal occurrence is indicated in Table 1. At 38-41 cm there is the base of a well preserved Betula tree stump whose remains and attitude leave no doubt that it is in situ, together with wood fragments of Quercus sp. Above the stump we find fibrous monocotyledonous peats and Sphagnum peat typical of blanket mires in upland Britain. This stratigraphy accords with the southern Pennine profiles in recording tree growth after a period of peat accumulation. In the lower peats (52-54 cm, 70-77 cm) the wood remains comprise fragments of birch bark and birch twigs, some of which are so large that they cannot have travelled far, and may represent in situ woodland.

Results from the pollen analysis of the basal 100 cm of the profile are displayed as Fig. 1, pollen frequencies being expressed as percentages of total land pollen. The strata described in the stratigraphic column are explained in Table 1, and above this sampled section lay a further metre of humified Sphagnum peat. In Fig. 1 certain taxa have been assembled into groups in accordance with their ecological affinities. 'Quercetum Mixtum' includes Quercus, Ulmus and Tilia. 'Heliophyte Shrubs' incorporates light-demanding woody taxa which respond favourably to forest canopy opening; Prunus, Sorbus, Salix and Fraxinus. 'Ruderals' includes herbs considered to be colonizers of waste or freshly cleared ground. Zonation of the pollen diagram is by a scheme of local forest clearance stages (FCS) of which three types are defined. Interference (I) phases recording

<sup>\*</sup> For 'soot' see Fig. 2.

low-intensity earlier clearance, clearance (C) phases recording higher-intensity later clearance and regeneration (R) phases during which forest clearance is considered not to be taking place. Radiocarbon dates are given in Table 2 and Fig. 1.

Correlation of the pollen and stratigraphical data reveals several interesting features. First, the relationship of the tree stump to a decline of *Ulmus* pollen: the other pollen frequencies, the <sup>14</sup>C date and comparison with other North York Moors pollen profiles suggest strongly that this is the *Ulmus* decline of western Europe, usually dated in this region to ~4,750 yr b.p. (ref. 3). If we accept this marker horizon and agree also that it is the spoor of the incursion of people of Neolithic culture, then the tree stump marks the end of Mesolithic time. Inspection of the pollen frequency curves for the 40–100 cm section of the profile reveals evidence corroborative of the interference with the vegetation suggested, particularly by the charcoal, in Table 1. This evidence takes the form of 'interference phases' of which three are recognized (I1, I2 and I3 on Fig. 1) and two of which are <sup>14</sup>C dated to the 5th millenium b.p.

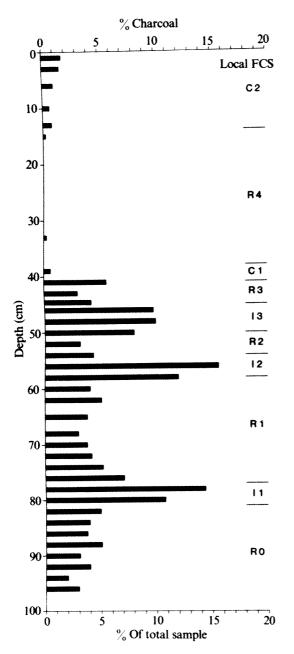

Fig. 1 Selective pollen diagram from Bonfield Gill Head, percentages of total land pollen. The stratigraphical units are identified and described in Table 1 and the FCS zones in the text (R, regeneration; I, interference; C, clearance).

Table 2 Preliminary results of radiocarbon determinations

		Radiocarbon age
Sample	No.	(yr b.p.)
I1 I2 I3 R4	HAR-4225 HAR-4226 HAR-4230 HAR-4229	$5,670 \pm 90$ $5,170 \pm 90$ $4,610 \pm 80$ $4,890 \pm 80$

We consider HAR-4230 to be anomalous and have ignored it in the

In the basal phase RO, Pinus sylvestris values are considerable, a feature common to early Flandrian II pollen spectra from the uplands of this region. Non-tree pollen values are also high, with Corylus, Salix and Gramineae prominent, as well as Pteridium spores. The subsequent pollen record implies that the open nature of the vegetation at this stage may be the legacy of an earlier episode of forest clearance, before the inception of peat formation at this site. From a peak at the base of the zone, non-tree pollen values decrease steadily as woodland regeneration continues. This trend towards more wooded conditions is abruptly reversed, however, during phase I1 (~5,670 yr b.p.), which marks the virtual demise of Finus sylvestris but sees distinct increases in Betula and Albus, with a sharp but temporary peak in the declining Corylus curve, echoed in the Pteridium spores. Fraxinus is recorded for the first time. Some ruderal pollen, including Melampyrum, Rumex, Cruciferae and Chenopodiaceae, show a first presence, or enhanced frequencies, as does a rather undifferentiated group like Rosaceae which may contain shrubs of open habitat. We interpret this interference phase as the result of forest necession associated with human activity4. Phase I1 is succeeded by a regeneration phase (R1) characterized, for example, by higher Quercus very high Betula, high Ulmus and Tilia levels, while Corylus and Fraxinus diminish, the latter to virtually nothing. With the exception of one horizon, Pteridium falls off in this phase as do ruderal pollen. Another I phase (I2, ~5,170 b.p.) follows at 55-58 cm, and then a short regeneration phase (R2) coinciding with a wood layer in the stratigraphy. The phases I2 and I3 are marked by especially high values for 'soot' and the fragments are sub-angular rather than rounded in shape, so that they may not have travelled far. Taxa like Corylus, Pteridium and heliophyte types Salix and Fraxinus all increase their frequencies in phase 12, while Melampyrum, Cirsium and Rumex are prominent among the ruderal herbs. Phase I3 (45-51 cm) records very abundant Pteridium and a large increase in the type and frequency of ruderal herbs, especially Melampyrum, Artemisia and Rumex, as well as frequencies for Calluna, which here exceed 100% of aggregate phase for the first time. This is presumably evidence for either a drier peat surface in the neighbourhood, or for the acidification of mineral soils, as it persists into regeneration phase R3. During the succeeding phase we detect the evidence of forest opening once again in the presence of Plantago lanceolata for the first time, along with high frequencies of Pteridium, Melampyrum and Betula: The pollen runs show that this phenomenon has a different character to the I phases and we have called it C1 (clearance 1). It is short lived and another R phase (R4) supervenes, to be interrupted by phase C2 near the op of the pollen diagram at a level where the sampling interval loes not permit its detailed discussion. The large Betula tree tump in the profile (~4,890 yr b.p.) corresponds with phase C1 ind the beginning of phase R4.

If the *Ulmus* decline marks the beginning of Neolithic sconomies in this region, then we should expect phases I1, I2 and I3 to result from Mesolithic man's activity. We infer that hey result from the burning of the woodland vegetation at or near the site as charcoal in the I phase is often quite large (15×9 mm pieces are found, for example). The 'soot' in the R phases probably came from burning in the region but far enough away to provide only background 'noise'. Even though doubts

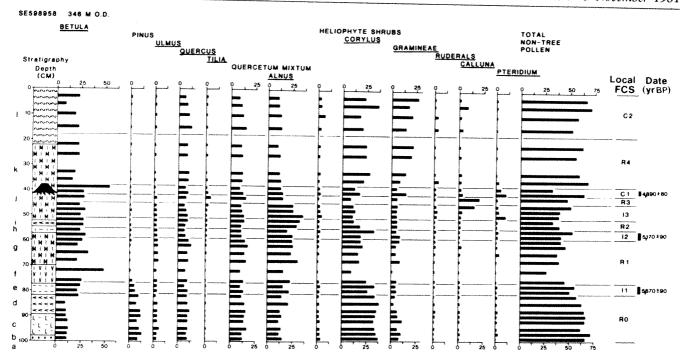

Fig. 2 Charcoal amounts at Bonfield Gill. The quantity of charcoal was estimated from disaggregated peat mixed with water which was spread over a gridded Petri dish. At  $\times 60$ , the percentage of each square ( $\Sigma = 100$ ) occupied by charcoal and carbonized material was estimated, J.B.I. estimates replicability to within ±3%. Note the correspondence with the I-phases identified from the pollen diagram (Fig. 1) and the lack of charcoal in R4: the post Ulmus decline phase on the pollen diagram.

have been expressed<sup>5</sup> on the interpretation of pollen diagrams in archaeological contexts, we believe that we have good evidence of repeated burning of the same site. The I-phase to I-phase interval is, however, longer than theory would predict<sup>2</sup> and more work is needed to see whether we are dealing with a real interval or whether we can improve the resolution of the technique: is R1 an aggregate phase, for example? Cessation of burning about the time of the Ulmus decline seems to have allowed tree growth and phases R1 and R2 could show smaller-scale evidence of the same feature. Even if the burning-recession sequence did not happen exactly here, it must have occurred in the near vicinity.

Finally, we caution that examination of many peat profiles from the North York Moors suggests that the Bonfield Gill site is unusual in its repetitive sequence, and that it is more common for wood to occur at the base of the blanket peat rather than above a sequence of peats and small wood fragments. While it may be that evidence of repeated burning, rather than the phenomenon itself, is patchy, it seems prudent to regard this practice as having had a limited spatial distribution. We emphasize, however, that the Bilsdale Moor area is said to have the highest density of Mesolithic flint sites in the country: this may be relevant circumstantial evidence. We suggest that here the burning seems to have stopped at the beginning of the Neolithic rather than later, as suggested for the southern Pennines; regional differences in occupance of the land by agricultural people could easily account for this point6.

We thank Dr Otlet of AERE Harwell for making the radiocarbon determinations and the British Academy for a grant towards their cost.

#### Successful biological control of the floating weed salvinia

P. M. Room\*, K. L. S. Harley†, I. W. Forno† & D. P. A. Sands\*

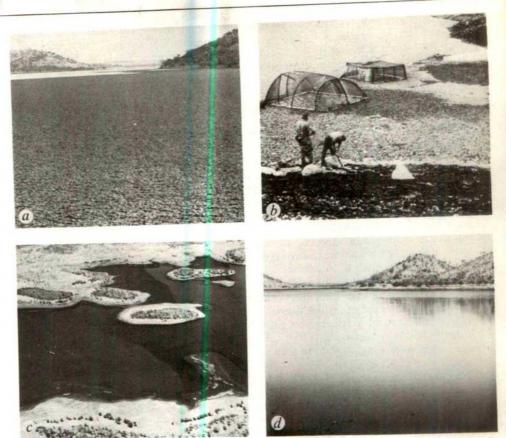

\* CSIRO Division of Entomology, Private Bag No. 3, Indooroopilly, Queensland 4068, Australia

† CSIRO Biological Control Unit, CP 322, Curitiba 80000, Parana, Brazil

The floating fern Salvinia molesta D. S. Mitchell (Salviniaceae) originated in southeastern Brazil<sup>1</sup>, but since about 1930, it has been introduced into various tropical and subtropical regions where it has become as great a menace as the water hyacinth<sup>2-4</sup>. Biological control of salvinia has clear economic and environmental advantages over other methods of control, but earlier attempts either failed or achieved inconclusive results<sup>5-7</sup>. We report here successful control of the largest salvinia infestation in Australia using the beetle Cyrtobagous singularis Hustache (Curculionidae) and suggest why this beetle has potential for controlling salvinia infestations elsewhere.

Salvinia was first recorded in Australia in 1952 and by 1976 it was present in many tropical and subtropical rivers and lakes and was more widespread than water hyacinth, which entered the country in the late 1800s8. Salvinia has achieved unacceptable population densities in Australia and elsewhere due to a combination of extremely high rate of growth, its dry weight doubling in 2.5 days in optimum conditions and an absence of suppressant parasites and pathogens8. By 1978 the largest infestation in Australia was on Lake Moondarra near Mt Isa, northern Queensland (20°36'S, 139°32'E), consisting of -50,000 tonnes fresh weight covering some 400 hectares (Fig. 1a). Attempts to control this infestation using herbicides

Fig. 1 S. molesta on Lake Moondarra in northern Queensland. a, In 1978. b, Weed damaged by C. singularis showed as dark patches on 20 January 1981, nearly 8 months after the beetles were released in and near the cages. c, The salvinia, forming a large mat to the left of the picture and smaller mats to the right of promontories, was under heavy attack by C. singularis and was uniformly dark brown on 17 May 1981. d, Most of the salvinia had been destroyed by 26 May 1981 (compare with a).

were abandoned in 1979 after expenditure of A\$160,000 (ref. 9).

The native range of *S. molesta* was unknown until 1978<sup>1</sup> and attempts at biological control until that time, in Africa, India, Sri Lanka and Fiji by the Commonwealth Institute of Biological Control, used insects found attacking the related *Salvinia auriculata* Aublet in northern South America and Trinidad<sup>5,7</sup>. In 1978, CSIRO Australia started a search for biological control agents in the newly discovered native range of *S. molesta* in southeastern Brazil. No new natural enemies were found, but local races of the three species of insect found by Bennett<sup>5</sup> to have potential for control were selected: *C. singularis*; the moth *Samea multiplicalis* (Guenée) (Pyralidae) which was released in northern Queensland in January 1981; and the grasshopper *Paulinia acuminata* (De Geer) (Pauliniidae) whose host specificity is being tested in quarantine in Australia.

Adult C. singularis are black, long-snouted weevils, about 2 mm long, which feed on salvinia buds. Eggs are laid among the submerged salvinia roots and larvae graze externally on roots before boring inside the rhizome.

Preliminary studies made in Brazil of *C. singularis* collected from *S. molesta* failed to detect any parasites or pathogens attacking the beetles, and to show whether the beetle could survive on plant species other than *S. molesta*. Eight hundred adults originally from Santa Catarina, Brazil, were then shipped to quarantine in Brisbane, Australia, where more detailed studies confirmed the absence of parasites and pathogens and the host specificity of *C. singularis*. Mass breeding was then started to obtain sufficient numbers for field releases.

On 3 June 1980 about 1,500 adults were released onto a salvinia-covered inlet on Lake Moondarra. About 500 beetles were introduced into each of two cages and the remaining 500 beetles were released immediately outside the cages. By late December, beetle activity had reduced salvinia cover by ~80% in the cages and caused discoloration of plants outside the cages. On 30 December fresh salvinia was added to the cages and the doors were left open.

Figure 1b shows the cages and the mouth of the inlet on 20 January 1981. The pale salvinia at the top left is healthy. A patch

of pale salvinia was blown around the square cage by strong winds the previous day and is nearly surrounded by darker salvinia damaged by *C. singularis*. Figure 2 shows the distributions of adult beetles and damage along a transect from the pale salvinia through the darker salvinia and further up the inlet. There was clearly a good correlation between the visual impression of damage from a distance and the proportions of leaves and buds damaged. It was also clear that beetles were moving away from heavily damaged salvinia, both onto newly available

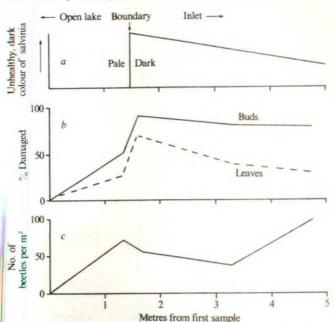

Fig. 2 Transect through the invasion front shown in Fig. 1b. a, Represents the sharp boundary between pale, healthy salvinia on the left and darker, unhealthy plants. b Shows the percentages of buds and leaves damaged by C singularis and c shows the numbers of adult C singularis per m<sup>2</sup> at five points along the transect.

undamaged plants and further up the inlet away from the population focus. No beetles or damage were found elsewhere on Lake Moondarra at this time.

On 20 January 1,500 more beetles were released onto salvinia about 300 m from the inlet and 10 large bags of beetle-infested salvinia were moved to the opposite side of the lake. A violent storm in February swept most of the remaining beetle-infested salvinia out of the inlet into the main body of the lake.

In late March salvinia throughout the lake started to turn brown and become waterlogged. On 18 April, all the salvinia was dark brown and samples taken at two sites 2 km apart contained respectively 60 and 80 adult C. singularis per m<sup>2</sup>, suggesting a total population of >100 million beetles. Population sizes of eggs, larvae and pupae were not estimated. Ninety-nine per cent of buds in both samples had been damaged. Damage was remarkably evenly distributed (Fig. 1c), suggesting an effective mode of beetle dispersal. A blacklight operated on the shore of the lake for 1 h from dusk was found to attract large numbers of strongly flying C. singularis.

By 26 May there was very little salvinia left (Fig. 1d). Three samples collected more than 1 km apart contained 100, 70 and 90 adult C. singularis per m<sup>2</sup>, which suggests a total population of about 6 million beetles. Ninety-nine per cent of the buds in each sample had been damaged.

Figure 3 presents estimates of the area and fresh weight of salvinia from August 1979 to 26 May 1981. The quantity of salvinia peaked in the autumn of each year until 1981. Drought starting early in 1978 reduced the autumn peak from 50,000 tonnes in 1978 to 19,000 tonnes in 1980 as the lake contracted in area to about 50% of maximum and salvinia was stranded. Substantial rain in January and February 1981 increased the area of the lake to ~80% of maximum and was expected to result in an autumn peak of 30,000 to 40,000 tonnes of salvinia. Some increase occurred to February 1981, after which C. singularis destroyed ~8,000 tonnes in 3 months and prevented significant regrowth. By August 1981 there was estimated to be <1 tonne of salvinia left. Despite the large quantity of salvinia killed and sunk, no algal blooms or other deleterious changes in water quality were detected (A. McCredie, personal communication). Based on analogous cases of biological control agents causing sudden collapses of dense populations of weeds<sup>10</sup>, we expect salvinia and C. singularis will be able to coexist on Lake Moondarra in a dynamic equilibrium at low population densities. However, both weed and control agent may become extinct on the lake if the remaining salvinia becomes stranded and dehydrated before the advent of the wet season in December 1981.

Why has C. singularis been so successful on Lake Moondarra, and has it the potential to control salvinia elsewhere? Attempts to establish the species on salvinia in Botswana and Zimbabwe in

the early 1970s failed5, as did attempts to breed it in Fiji7. In these cases the beetles used were collected from S. auriculata in Trinidad, whereas the plant on which establishment was attempted was S. molesta. Although taxonomists recognize beetles collected from both species of plant as C. singularis, the Australian success may be due to our having obtained a race particularly adapted to S. molesta. If this is the case, we may have solved the intractable problems caused by S. molesta in Africa<sup>2,11</sup>, India<sup>2,4</sup>, Sri Lanka<sup>2</sup>, Indonesia<sup>2</sup>, Papua New Guinea<sup>3</sup>, New Zealand and Fiji<sup>7</sup>, and elsewhere in Australia.

#### Enkephalin as a transmitter for presynaptic inhibition in sympathetic ganglia

#### Shiro Konishi, Akinobu Tsunoo & Masanori Otsuka

Department of Pharmacology, Faculty of Medicine, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo 113, Japan

The endogenous opioid peptides, enkephalins, are known to be concentrated in discrete populations of central and peripheral neurones<sup>1-3</sup> and to inhibit synaptic transmission through a presynaptic mechanism reducing the release of transmitters<sup>4-6</sup>. These observations led to a hypothesis that enkephalin may serve as a transmitter for presynaptic inhibition at central and peripheral synapses<sup>4,5</sup>. To substantiate this hypothesis it is of crucial importance to demonstrate at specified synapses an inhibitory process that is evoked by stimulation of enkephalincontaining nerve fibres and is blocked by the opiate antagonist, naloxone. Mammalian sympathetic ganglia may provide a useful model for exploring this possibility, because enkephalin was shown, using immunohistochemistry<sup>3</sup>, to exist in certain nerve terminals in the ganglia and to inhibit cholinergic and noncholinergic transmission by a presynaptic mechanism<sup>5,7,8</sup>. We now report that in mammalian prevertebral ganglia, the conditioning stimulation given to preganglionic nerves produces a longlasting presynaptic inhibition of cholinergic transmission and that this inhibition is specifically abolished by naloxone. The results strongly suggest that enkephalin or closely related peptide(s) liberated from certain preganglionic fibres act as a transmitter for presynaptic inhibition, regulating the release of acetylcholine (ACh) in the sympathetic ganglia.

Experiments were carried out on the inferior mesenteric ganglia isolated from adult guinea pigs. The ganglion was placed in a bath and perfused with modified Tyrode solution at 36 °C. Intracellular recordings were made from ganglion cells as described previously<sup>5,8</sup>. Test stimuli were given to a small bundle of the lumbar splanchnic nerve through a suction electrode to evoke cholinergic fast excitatory postsynaptic potentials (e.p.s.ps). To the remaining preganglionic nerves, that is, the lumbar splanchnic and/or intermesenteric nerves,

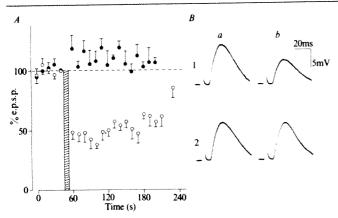

Fig. 1 Inhibitory effect of conditioning stimulation on cholinergic e.p.s.ps recorded from neurones in the inferior mesenteric ganglia, and antagonism by naloxone. Test e.p.s.ps were evoked by stimulating a small bundle of the lumbar splanchnic nerve at 1 Hz. Conditioning stimulation at 50 Hz for 8 s was given to the remaining lumbar splanchnic nerves during the period shown by the hatched column in A. A, eight successive e.p.s.ps were averaged every 10 s and recorded (see sample records in B). The amplitude of each averaged e.p.s.p. was expressed as a percentage of the control that was recorded immediately before the conditioning stimulation. Each point and vertical bar represent the mean ± s.e.m. obtained from three successive observations repeated at 6-min intervals on the same neurone. O, In control solution; and O, in the solution containing naloxone (3 µM). B, sample records of the averaged e.p.s.ps in another experiment. a, Test responses during the control periods; and b, conditioned responses obtained during the 15-20 s after the end of conditioning stimulation (50 Hz for 8 s). 1, In control solution; and 2, in the presence of naloxone  $(3 \mu M)$ .

conditioning stimulation was given with one or two separate suction electrodes.

Since the enkephalin-containing nerve terminals in the prevertebral sympathetic ganglia are thought to originate mainly from the preganglionic fibres  $^{3.9}$ , we sought to establish whether stimulation of preganglionic nerves produces an inhibitory effect on the cholinergic fast e.p.s.ps. After conditioning stimulation (50 Hz for 8 s), the amplitude of signal-averaged test e.p.s.ps was reduced to <50% of the averaged size of control e.p.s.ps, and the inhibition lasted for 2-4 min (Fig. 1). Such a prolonged inhibitory effect became obvious with the conditioning stimulation at 50 Hz for 2 s, and its magnitude depended on the number of conditioning stimuli. The maximal extent and the half-decay time of the inhibition produced by the preganglionic stimulation (50 Hz for 8 s) were  $70.5\pm4.7\%$  and  $56.4\pm5.8$  s respectively (mean  $\pm$ s.e.m. in 12 cells).

The inhibitory effect of the conditioning preganglionic stimulation on cholinergic e.p.s.ps was abolished by addition of naloxone (1-3 μM) (Fig. 1). Naloxone in the same concentration range almost completely blocked the inhibitory action of a potent enkephalin analogue, [D-Ala<sup>2</sup>]-Met-enkephalinamide  $(0.3-2 \mu M)$ , on cholinergic e.p.s.ps<sup>7</sup>. To test the specificity of the action of naloxone, we examined its effects on the inhibition produced by other substances. Noradrenaline (10-50 µM), dopamine (20-100  $\mu$ M) and  $\gamma$ -aminobutyric acid (20-50  $\mu$ M) depressed the cholinergic e.p.s.ps in the sympathetic ganglia<sup>10-12</sup>, but the inhibitory effects of these substances were not affected by naloxone (3  $\mu$ M). An  $\alpha$ -adrenergic blocker, phentolamine  $(1.5-3 \mu M)$ , on the other hand, abolished the effect of noradrenaline, but did not affect the neurally evoked inhibition of cholinergic fast e.p.s.ps. Furthermore, this inhibition remained unchanged in the presence of atropine (2 µM). Therefore, it is unlikely that catecholamine-containing interneurones are involved in this inhibitory process<sup>13</sup>

Further experiments were carried out to determine whether the mechanism of this inhibition is pre- or postsynaptic. The sensitivity of the postsynaptic membrane to ACh and the input resistance of ganglion cells were determined before and after conditioning stimulation. In the experiment shown in Fig. 2, both the sensitivity, to ACh and the membrane resistance of a ganglion cell increased slightly 10-60 s after the end of conditioning preganglionic stimulation (50 Hz for 8 s). In contrast, during the same period, the mean size of e.p.s.ps recorded from the same neurone was reduced to 15-60% of the control (Fig. 2a). The slight increase in the ACh-induced depolarization as well as in the membrane resistance may be due to the noncholinergic slow e.p.s.p. produced by preganglionic stimulation? These results can be explained by the hypothesis that the neurally evoked inhibition is caused mainly by a presynaptic mechanism reducing the amount of ACh release.

This hypothesis was further supported by quantal analysis of the e.p.s.ps during the control and conditioned periods (Fig. 3). On an assumption that the quantal release of ACh can be predicted by Poisson statistics<sup>14,15</sup>, the mean number of ACh quanta released by each test stimulus was estimated from the number of failures in a series of trials. During the period 10-170 s after conditioning stimulation (50 Hz for 12 s), the number of failures showed a ninefold increase over that observed during the control period (stippled columns in Fig. 3; see also Fig. 2a) and the mean quantum content of the e.p.s.ps was reduced to about 40% of the control. In contrast, the estimated size of the quantal unit did not change significantly after the conditioning stimulation (arrows in Fig. 3). Essentially the same results were obtained in eight other experiments, where the conditioning preganglionic stimulation (50 Hz for 8-12 s) reduced the mean quantum content to  $54.7 \pm 3.5\%$  of the control (mean ± s.e.m.) while the unit size of e.p.s.ps during the conditioned period was  $107.7 \pm 5.2\%$  of the control. The results, therefore, support the presynaptic nature of this neurally evoked inhibition. The effects of conditioning stimulation in increasing the number of failures and reducing the quantum content of e.p.s.ps were also reversed by naloxone (Fig. 3c). Naloxone alone, however, did not significantly affect the unit size or mean size of e.p.s.ps (Fig. 1B).

The present findings, together with other lines of evidence with regard to the action and the presence of enkephalin<sup>3,5</sup>,

#### Breakdown of cytoskeletal filaments selectively reduces Na and Ca spikes in cultured mammal neurones

Jun Fukuda, Masaki Kameyama\* & Kazuhiko Yamaguchi

Department of Physiology, Faculty of Medicine, University of Tokyo, Bunkyo-ku, Tokyo 113, Japan

Cytoskeletal filaments, which contain microtubules <sup>1-4</sup> (~25 nm thick), microfilaments<sup>5,6</sup> (5 nm) and intermediate filaments<sup>7-9</sup> (neurofilaments, 10 nm), are considered essential for maintaining complex cellular shape and various cellular functions. Several studies have claimed that these filaments also maintain in some part physiological properties of excitable membranes<sup>10-14</sup>. However, the role of these filaments in maintenance of ionic channel activity is poorly understood 10,11. Here we report experiments in which we disrupted specific cytoskeletal filaments by applying chemicals to tissue-cultured nerve cells of adult guinea pigs<sup>15-17</sup>, and examined changes in membrane properties by conventional electrophysiological techniques. Selective breakdown of microfilaments by cytochalasin B<sup>5,6,18-21</sup> or its derivatives<sup>22-24</sup> caused selective reduction in the membrane capacity to carry Na ions 16 (as measured by  $\dot{V}_{\rm max}$  of pure Na spikes). The ability of the membrane to carry Ca ions1 and other physiological properties (resting membrane potential, input resistance and capacitance) were not affected significantly. By contrast, a breakdown of microtubules by colchicine  $^{1-4}$  or vinca alkaloids  $^{4,25}$  caused selective reduction of  $\dot{V}_{\rm max}$  for Ca spikes but not of that for Na spikes. These findings suggest that Na channels in the plasma membrane may have a molecular interaction with microfilaments, but are independent of microtubules. Conversely, Ca channels may be related to microtubules or to neurites, but seem to be independent of microfilaments.

The techniques used in tissue culture of nerve cells from adult guinea pigs have been reported elsewhere 15-17. Dorsal root ganglia were incubated with collagenase in L-15 medium, and nerve cells isolated from the ganglia by vibration. The nerve cells were grown in collagen-coated plastic dishes on growth medium (75% Eagle's medium, 15% fetal calf serum, 9% chick embryo extract and 1% penicillin-streptomycin solution) in air containing 5% CO2 at 37°C.

After 2 days of culture, cytochalasin B and colichicine, prepared as described below, were added to the tissue culture dishes (1.5 ml growth medium per dish) using a microsyringe. At this stage of culture, nerve cells were starting to extend their neurites 15,17 (Fig. 1a). Cytochalasin B (1 mg) was first dissolved in dimethyl sulphoxide (DMSO, 1 ml), then diluted with L-15 medium to give a final concentration in stock solution of

All values are mean  $\pm$  s.d.; numbers of neurones examined are indicated in parentheses. The nerve cells were immersed in a  $\text{Co}^{2+}$ - and  $\text{TEA}^+$ -containing medium (see Fig. 2 legend), in which the nerve cells generated pure Na spikes. Input resistance and capacitance were obtained by intracellular passage of a small hyperpolarizing pulse current (up to 0.3 nA for 16 ms), assuming that the membrane was a single resistance-capacitance circuit. Pure Na spikes were elicited, as seen in Fig. 2;  $\dot{V}_{\text{max}}$  of the spikes were obtained by electronic differentiation. Before passage of pulse current the membrane potential of the penetrated nerve cells was held at  $\sim -100 \, \text{mV}$ , where the current-voltage relationship is approximately linear and the membrane generates a full-sized Na spike. Note that no change was induced in resting membrane properties of the nerve cells after exposure to cytochalasin B and colchicine.

P < 0.01; † P < 0.001 (Student's t-test).

100 μg ml $^{-1}$ . Dihydrocytochalasin B $^{23,24}$  and cytochalasin D $^{22}$  were prepared in the same way. Control solutions consisted of either L-15 medium alone or L-15 medium containing 10% DMSO. Colchicine, vinblastine sulphate, vincristine sulphate and colcemide were stored as solutions (2 μM) in L-15 medium. Control solutions for these alkaloids were either L-15 medium alone or L-15 medium containing 800 μg ml $^{-1}$  (2 μM) lumicolchicine (prepared by UV illumination of colchicine dissolved in 99% ethanol $^{25}$ ).

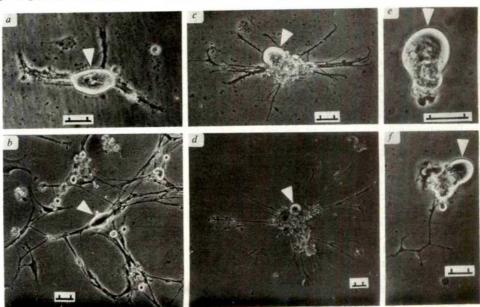

Cultured nerve cells were penetrated by a glass micro-electrode  $(20\text{--}30~\text{M}\Omega)$  filled with 3 M KCl. To elicit spikes and measure membrane resistance and capacitance, d.c. and pulse currents (up to 5 nA) were passed intracellularly through the microelectrode. The intracellular potential was determined by a Wheatstone bridge balance. Input resistance and capacitance were measured using a small pulse current while holding the membrane potential at  $\sim -100~\text{mV}$ ; the nerve cell was assumed to be a single RC circuit<sup>16</sup>. Na and Ca spikes were elicited using depolarizing pulses. Pure Na spikes were elicited in nerve cells bathed in a Co<sup>2+</sup>-containing solution (see ref. 16 and Fig. 2 legend); Co<sup>2+</sup> was added to inhibit Ca spikes<sup>26</sup>, which otherwise are superimposed on the Na spikes. Pure Ca spikes were elicited in nerve cells bathed in a Na-free tetraethylammonium(TEA)-containing solution (see ref. 15 and Fig. 2 legend). Before spike

initiation, the membrane potential of the penetrated nerve cell was hyperpolarized to a potential more negative than  $-100~\rm mV$ . This continuous hyperpolarization eliminated inactivation of Na and Ca channels which occurs at a small resting membrane potential  $^{15-17}$  (Table 1). The  $\dot{V}_{\rm max}$  of a full-sized spike elicited during the hyperpolarization was obtained by electronic differentiation; this  $\dot{V}_{\rm max}$  was considered proportional to the largest amplitude of inward Na or Ca currents in the membrane  $^{27}$ , and was compared for nerve cells grown in different conditions.

Cytochalasin B caused several distinct morphological changes in nerve cells (Fig. 1c, d). (1) Growth of neurites was reduced at a low dose ( $4 \mu g \, \text{ml}^{-1}$ ) and suppressed at the higher dose of  $12 \, \mu g \, \text{ml}^{-1}$ : nerve cells tended to have fine neurites that were relatively short. (2) Neuronal somata became spherical; and (3) within a few days of exposure, the nerve cell population was reduced (2/3 to 1/2) due to loss of nerve cells from the monolayer. (4) Growth of fibroblasts and Schwann cells was inhibited. These changes can be regarded as selective breakdown of microfilaments by cytochalasin  $B^{5,6,18-21}$ . DMSO alone, added as a control, caused no significant morphological or population change in both neuronal and glial cells (results not shown).

Intracellular recordings of nerve cells exposed to cytochalasin

Fig. 1 Changes in morphology of cultured nerve cells after exposure to cytochalasin B or colchicine. a. Nerve cell which, after 2 days in tissue culture, started to extend neurites from the somata (triangle). b. Control nerve cell (triangle) after 4 days of culture. c, d, Neurones after exposure to cytochalasin B. These cells were maintained in culture for 4 days, and exposed to cytochalasin B at a concentration of 12 µg ml<sup>-1</sup> or 4 µg ml<sup>-1</sup> (d) during days 2 to 4. Note the sparse neurite growth compared to control cells (b). e, f, Neurones exposed to colchicine (16 µg ml<sup>-1</sup>) during days 2 to 4 of tissue culture. Most nerve cells became spherical (e). Some cells had fine neurites of a very short length (f). Calibration bars: 20 μm.

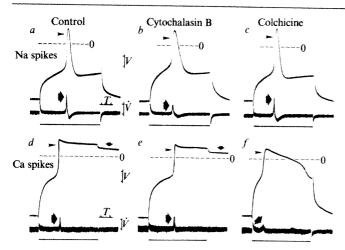

Fig. 2 Na and Ca spikes elicited in cultured nerve cells exposed to cytochalasin B or colchicine. Na spikes (wedges in a-c) and Ca spikes (wedges in d-f), elicited in normal cells (a, d), cytochalasin B-treated cells  $(4 \mu g ml^{-1}; b, e)$  and colchicine-treated cells  $(16 \mu g ml^{-1}; c, f)$ . All nerve cells were maintained in vitro for 4 ; c, f). All nerve cells were maintained in vitro for 4 days, and were exposed to the chemicals during days 2 to 4 of tissue culture. Na spikes were elicited in nerve cells in medium containing 141 mM NaCl, 1 mM CoCl<sub>2</sub>, 1 mM CaCl<sub>2</sub>, 10 mM TEA-Cl, 5.5 mM KCl, 5.5 mM glucose and 2 mM Na-HEPES at pH 7.4. Ca spikes were elicited in Na-free medium containing 80 mM TEA-Cl, 63 mM Tris-HCl, 10 mM CaCl<sub>2</sub>, 5.5 mM KCl and 5.5 mM glucose, pH 7.4. Downward arrows in d and e show that overshoots of Ca spikes were still present even after cessation of depolarizing pulse-current passage. However, Ca spikes in colchicine-treated nerve cells were of short duration (f). Lower traces of a-f were obtained by electronic differentiation of the upper intracellular records.  $V_{\text{max}}$  of the spikes (arrows) were considered to be proportional to transient inward Na or Ca currents associated with the respective spikes. Bars underneath indicate the duration of depolarizing pulse currents passed intracellularly. Calibrations: T, 2 ms for a-c and 20 ms for d-f; V, 20 mV for a-f;  $\dot{V}$ , 80 V s<sup>-1</sup> for a-c and  $10 \text{ V s}^{-1}$  for d-f. Further details are given in the text.

B for 1-2 days revealed resting membrane properties (resting potential, input resistance and capacitance, and I-V relationship) that were very similar to those of normal nerve cells (Table 1). The nerve cells were also capable of generating both Na and Ca spikes (Fig. 2b, e). The most remarkable effect of cytochalasin B exposure was a selective reduction in  $\dot{V}_{\rm max}$  of the Na spikes (arrow in the lower trace of Fig. 2b, and Table 1). This reduction, which was small at 6 h (85% of normal value, P< 0.2), became apparent (P < 0.01) in 2 days (Table 1). A higher dose of cytochalasin B induced a larger reduction in a shorter period (Table 1). However, this was associated with a great loss of cells. This reduction in the  $V_{\text{max}}$  of the Na spikes disappeared 2 days after removal of cytochalasin B from the growth medium (data not shown). Similar specific reduction in the Na spikes was induced by dihydrocytochalasin B and cytochalasin D (results not shown) which also cause breakdown of microfilaments<sup>22-24</sup> By contrast, there was no change detected in Ca spikes (Fig. 2e and Table 1), even when dose and time of exposure to cytochalasin B were increased. These results indicate that the mechanisms required to generate Ca spikes are independent of microfilaments.

Exposure of the cultured nerve cell to colchicine  $(16 \ \mu g \ ml^{-1})$  for 2 days caused retrogression of neurites (Fig. 2c, f), and produced spherical somata and a reduction in nerve cell population. Colchicine inhibited growth of fibroblasts and Schwann cells on the dishes, which can be explained by a breakdown of microtubules by colchicine<sup>1,3,4</sup>. Lumicolchicine  $(128 \ \mu g \ ml^{-1})$ , added as a control, did not change neuronal and glial morphology (results not shown). The most remarkable changes in membrane properties effected by colchicine were a small  $V_{\rm max}$  and a short duration of Ca spikes (Fig. 2f and Table 2). These changes in the Ca spikes appeared within 1–2 days of colchicine application, but disappeared 3 days after its removal (not

shown). A higher dose of colchicine or a longer period of exposure resulted in only a slightly smaller  $\dot{V}_{\rm max}$  (Table 2). By contrast, no statistically significant change (P < 0.2) was observed for Na spikes (Fig. 2c, Table 1), resting potential, input resistance and capacitance (Table 1). A similar specific reduction in  $\dot{V}_{\rm max}$  of the Ca spikes was induced by other vinca alkaloids (vinblastine, vincristine and colcemide; data not shown)—these also disrupt microtubules  $^{1-4.25}$ .

These experiments demonstrate that, even though cytochalasin B and colchicine induce drastic changes in cell morphology, many nerve cells exhibit healthy electrophysiological properties. In particular, the lack of significant change in input resistance and capacitance (first order approximation) indicates that the basic structure and function of the plasma membrane seem to be maintained. Assuming that capacitance of unit area of the plasma membrane remained unchanged, the small  $\dot{V}_{\rm max}$  of the Na spikes induced by cytochalasin B is considered to be due to a reduction in inward Na currents<sup>27</sup> which may be explained further as a reduction in Na channel density in the membrane or as a conformational change in Na channels. Reduction in electromotiveforce of Na current does not seem to be a main cause because Na spikes in the cytochalasin B-treated nerve cells showed a large overshoot or, for a few cells, only a small reduction in spike amplitude (threshold to peak) of ~10 mV. It is highly unlikely that K currents were increased by cytochalasin B because the K conductance should, in part, affect Ca spikes.

The selective reduction in Na spikes by cytochalasin B suggests an interaction between microfilaments and Na channel molecules<sup>10</sup>. However, this interaction may not always be simple, as at least 24 h are required to induce an apparent change in the Na spikes. Possible interactions are: (1) microfilaments may constitute major anchoring filaments of Na channel molecules in the plasma membrane; (2) microfilaments may be involved in transportation of Na channel molecules into the plasma membrane; (3) they may contribute to synthesis of Na channels in nerve cells. By contrast, the fact that colchicine had little effect on Na spikes indicates that the Na channels in the membrane may be independent of microtubules<sup>11</sup>.

The reduced Ca spike caused by colchicine treatment of nerve cells suggests an interaction between microtubules and Ca channel molecules: that is, microtubules may contribute to maintaining Ca channels in the plasma membrane, for example, as an anchoring cytoskeletal filament. However, some observations do not conform to this idea. First, electron-microscopical observations have generally failed to demonstrate microtubules at presynaptic nerve terminals, which are presumed to be rich<sup>26,28</sup> in Ca channels. In a few studies where microtubules are found in nerve terminals, they seem to be

Table 2 Changes in Ca spike component of cultured nerve cells exposed to cytochalasin B and colchicine

		$\dot{V}_{\max}$ of Ca spikes $(\mathbf{V}  \mathbf{s}^{-1})$	Ratio
Cytochalasin B Control Cytochalasin B Control	(6 μg ml <sup>-1</sup> , 2 days) (DMSO) (10 μg ml <sup>-1</sup> , 3 days) (L-15)	$4.8 \pm 2.5 \ (n = 12)$ $4.9 \pm 1.8 \ (14)$ $8.0 \pm 2.1 \ (11)$ $8.7 \pm 2.8 \ (8)$	0.98 0.92

Ca spikes were elicited in nerve cells immersed in a Na-free, TEA<sup>+</sup>-rich medium, as seen in Fig. 2. All values are mean ± s.d.; numbers of sampled nerve cells are indicated in parentheses. Note that there was no significant change in Ca spikes for nerve cells exposed to cytochalasin B. For further details see text.

<sup>\*</sup> P < 0.02; † P < 0.01 (Student's *t*-test).

related to synaptic vesicles but not to the plasma membrane<sup>29</sup> Second, microtubules are easily depolymerized by Ca ions<sup>4,30</sup> which pass through the Ca channels. Thus, we cannot exclude the possibility that the change in the Ca spikes may be due to wide changes in cellular structure, such as changes in cell shape. Indeed, Ca spikes become large during growth of neurites in tissue culture 15, and are considered to form major action potentials in dendrites of cerebellar Purkinje cells31. Thus, the small Ca spikes may be due to a loss of neurites caused by microtubule breakdown after colchicine treatment of the nerve cells

#### Immunochemical and immunocytochemical localization of S-100 antigen in normal human skin

#### Domenico Cocchia, Fabrizio Michetti & Rosario Donato

Department of Anatomy, Università Cattolica, 00168 Roma, Italy

The S-100 antigen1 is generally considered to be unique to the nervous system, where it is found primarily in the cytoplasm and nucleus of glial cells, both in soluble and bound form<sup>2,3</sup>. It belongs to the family of acidic Ca2+-binding proteins4. In phylogenesis, S-100 conserves a close immunological relationship between different species, and during ontogenesis the pattern of its accumulation parallels the functional maturation of the nervous system<sup>2,3</sup>, although its biological role remains to be clarified. Recently, S-100 has been found in cells of non-nervous organs (interstitial cells of the pineal gland5, stellate cells of the adenohypophysis<sup>6,7</sup> and satellite cells of the adrenal medulla<sup>8</sup>), and in cultured malignant human melanomas?. We report here the presence of S-100 in normal human skin, where the antigen seems to be located specifically in melanocytes and in cells with morphological features of Langerhans cells.

Table 1 S-100 protein concentration in normal human skin and malignant human melanoma

	μg S-100 per mg soluble
Tissue	protein
Normal skin Malignant melanoma	0.03 1.90

Normal human skin (0.5 g per experiment) and malignant human melanoma (1.0 g per experiment), tested by histopathology, were obtained from the neck and leg during surgery (three specimens each of normal human skin and human melanoma). The tissues were homogenized in a glass homogenizer in 10 mM Tris-HCl, pH 7.4 (1:4 w/v), containing 0.1 mM phenylmethylsulphonylfluoride (Sigma) to minimize proteolytic degradation<sup>21</sup>. The homogenates were centrifuged at 105,000g for 60 min at 4 °C and the supernatants analysed for total protein by the method of Lowry et al.<sup>22</sup>, and for S-100 content by microcomplement fixation<sup>10</sup> using as a standard ox S-100 purified as described by Moore1. Samples with complement alone and with both complement and antiserum were assayed to test the anticomplementary activity of tissue extracts and antiserum. S-100 values are expressed in terms of ox S-100 equivalents. All measurements were performed in duplicate; all values were corrected for anticomplementary activity, when present. The antiserum was diluted 1:500 before the assay. Maximal s.e.m. was  $\pm 5\%$  (n = 3). The bound fraction was not evaluated.

Levels of S-100 were measured by microcomplement fixation assay10, both in normal skin and, for comparison, in human melanomas, using a specific antibody raised against ox S-100 and characterized as described elsewhere<sup>11</sup>. Cross-reactivity between ox and human S-100 protein has been observed<sup>11,12</sup>. The complete complement fixation curve for extracts of normal human skin and a standard curve of S-100 protein are shown in Fig. 1a, b. The amounts of S-100 were measured in samples containing 15 or 25 µg total protein (~100-165 µg protein ml-1); no appreciable anticomplementary activity was observed at these concentrations. The S-100 antigen was detected in measurable amounts in both normal skin and melanoma, with an ~80 times higher concentration in the latter than in the former (Table 1). The concentration of S-100 in the skin seemed to be ~100 times lower than that reported for the human brain9.

The cellular and subcellular localization of S-100 in normal human skin was also investigated by electron microscopy using unlabelled antibody PAP method13 with the same

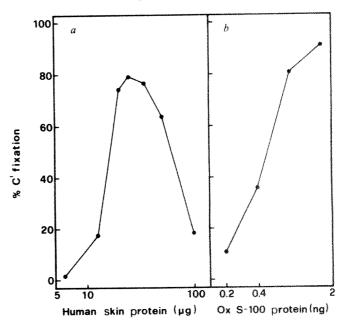

Fig. 1 Representative complement (C') fixation curves of S-100 from normal human skin (a), and of purified ox S-100 (b). Normal skin extract and purified S-100 were prepared, and quantitative complement fixation performed as described in Table 1 legend. All values were corrected for anticomplementary activity, when present.

antiserum. In the epidermis, S-100 reaction product was detected in the perikarya and in the cytoplasmic processes of both melanocytes and Langerhans cells (Fig. 2a, b). No reaction product was present in the keratinocytes of any epidermal layer (Fig. 2a). Merkel cells were not observed in our preparations. In the dermis, S-100 reaction product was detected not only in typical Langerhans cells (which appeared as elongated cells with indented nuclei and slender processes lying close to the other cell types, exhibiting the distinctive cytoplasmic granules; Fig. 2c), but also in cells with ultrastructural features comparable with Langerhans cells but lacking the characteristic granules (Fig. 2d). It is possible that these are Langerhans cells having granules that are not detectable in the plane of the section, or 'histiocytes' or 'dermal macrophages' having the latent capacity to become manifest as dermal Langerhans cells by production of the characteristic granules14. Fibroblasts and collagen fibres, lymphocytes, vascular endothelial cells and pericytes had no reaction product. Melanocytes and nerve fibres were not detected in the dermis.

The subcellular distribution of the antigen was the same in all the S-100-immunoreactive cells. Immunoreactivity was widely distributed in the cytoplasmic matrix but absent from the cisternae of the endoplasmic reticulum and the Golgi apparatus, as well as from the plasma membranes and mitochondria (Fig. 2a-d). Melanosomes and Langerhans granules also appeared free of reaction product (Fig. 2a-c). In the nucleus, immunoreactivity was found in the nucleoplasm but not in the nucleolus or the nuclear envelope (Fig. 2a, b, d). Control experiments carried out using preimmune rabbit serum or anti-S-100 antiserum absorbed with the antigen did not show any

reaction product (Fig. 3a, b). Thus the distribution of the antigen in immunoreactive cells of the skin seems similar to that reported for S-100-immunoreactive cells of nervous  $^{15.16}$  and non-nervous organs  $^{5-8}$ .

Our findings agree with recent observations on the presence of S-100 in malignant human melanomas<sup>9</sup>. In addition, they indicate that definite cutaneous cell types normally contain significant amounts of the antigen, but at a much lower concentration than in malignant tissue. No detectable amounts of antigen in normal human skin were reported by Gaynor et al.<sup>9</sup> as tested by microcomplement fixation assay; this discrepancy could be accounted for by use of different titres of antisera. The presence of S-100 in normal melanocytes rules out the possibility of the protein being regarded as a marker unique to malignant melanocytes. In this respect, detailed studies will be needed to establish any possible relationship between levels of S-100 and the degree of malignancy of melanomas, as reported for human tumours of glial origin<sup>17</sup>.

The presence of S-100 in melanocytes agrees with the neuro-ectodermal origin of this cell type <sup>18,19</sup>. On the other hand, the observation that Langerhans cells contain S-100 is intriguing, as these are generally believed to be mesodermal in origin <sup>18,20</sup> and data on the cellular localization of S-100 indicate that the protein is present in cells commonly considered to be of neuro-ectodermal origin <sup>2,3</sup>. It is also possible that Langerhans cells take up S-100 passively, although the distribution of the antigen both in the cytoplasm and the nucleus, similar to that observed in other S-100-immunoreactive cells <sup>5-8,15,16</sup>, seems to oppose this view.

Our present data, together with the recent findings of S-100

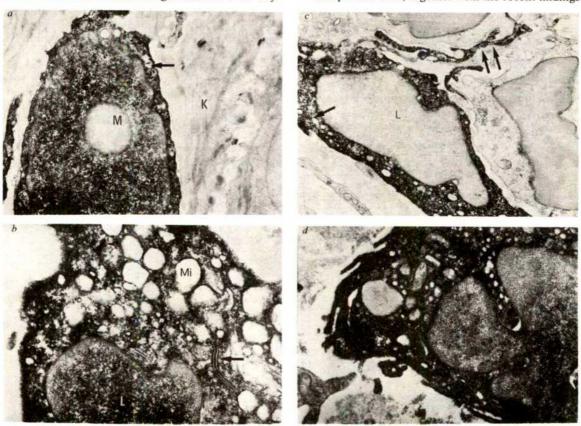

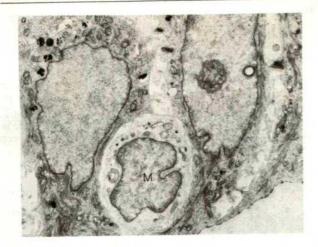

Fig. 2 Sections of normal human skin reacted with anti-S-100 antiserum. Normal human skin obtained from the neck or leg regions during surgery on three patients was fixed in 4% paraformaldehyde in 0.1 M phosphate buffer for 3 h, washed in phosphate-buffered saline (PBS) overnight and then sectioned on a Sorvall TC-2 chopper. The sectioned slices were treated with anti-S-100 antiserum diluted in PBS at 1:500, using the unlabelled antibody PAP method as described elsewhere<sup>8</sup>. a, The melanocyte (M) is labelled in the nucleoplasm as well as in the cytoplasmic matrix. No reaction product is present in the nucleoplas and in melanosomes (arrow). The keratinocytes (K) do not show any reaction product. b, The epidermal Langerhans cell (L) shows immunoreactivity in the nucleoplasm as well as in the cytoplasmic matrix. The mitochondria (Mi) and the typical cytoplasmic organelles (arrow) are free of reaction product. c, The dermal Langerhans cell (L) with the distinctive organelles (arrow) shows reaction product in the cytoplasmic matrix. No reaction product is detectable in the nucleus, possibly due to insufficient penetration of antibodies during the immunocytochemical procedure, as also observed elsewhere <sup>7,8,16</sup>. Labelled Langerhans cytoplasmic processes (double arrow) are closely related to other cell types which seem to lack immunoreactivity. d, The dermal Langerhans-like cell shows S-100 immunoreactivity in the nucleoplasm as well as in the cytoplasmic matrix. a, ×11,400; b, ×23,000; c, ×11,400; d, ×18,300.

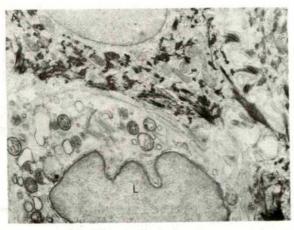

Fig. 3 Control sections of normal human skin treated as described in Fig. 2 legend but reacted with anti-S-100 antiserum absorbed with S-100 antigen. Neither the melanocyte (M) nor the epidermal Langerhans cell (L) show any reaction product. The same results were obtained when sections were treated with normal preimmune rabbit serum. a, ×9,400; b, ×14,300.

antigen in non-nervous organs in normal conditions5-8, suggest that S-100 should no longer be considered strictly as a protein specific to the nervous system. Further studies on the general tissue distribution of S-100 will be needed to clarify whether the protein is confined to cell types of common embryonic origin.

This work was partially supported by CNR contract no. 80.00515.04. We thank Drs G. Fortunato and F. Landi for supplying samples of normal skin and malignant melanoma, Professor N. Miani for critical review of the manuscript and Miss C. Annibaldi for secretarial assistance.

#### Isoleucine-requiring Nicotiana plant deficient in threonine deaminase

Vladimir Sidorov\*, László Menczel & Pál Maliga†

Institute of Plant Physiology, Biological Research Centre, Hungarian Academy of Sciences, PO Box 521, Szeged H-6701, Hungary

Well characterized auxotrophic mutants would greatly assist the genetic manipulation of flowering plants, but such mutants are rare1-3. Moreover, auxotrophic mutants isolated at the plant level4-8 and some of those isolated in cell cultures9 are leaky. The isolation of the first non-leaky auxotrophic mutant, requiring a source of nitrogen in reduced form, was possible by direct selection for chlorate resistance of this rare mutant type 10. A different approach, the individual testing of colonies grown from mutagenized haploid cells of Datura 11 and Hyoscyamus 12, has resulted in cell lines with absolute nutritional requirement. We report here the isolation of an isoleucine-requiring line from haploid cell cultures of Nicotiana plumbaginifolia and the regeneration of diploid plants. These plants have no detectable activity of L-threonine deaminase (EC 4.2.1.16), the first enzyme in isoleucine biosynthesis.

Haploid protoplasts were prepared from leaves of N. plumbaginifolia plants, mutagenized by irradiation and grown to small colonies in complete medium. Calli derived from nonirradiated protoplasts were not studied. Two out of 11,049 colonies tested after mutagenesis were unable to grow on minimal medium (Table 1); they were later identified as a uracil (URA401) and an isoleucine (ILE401)-requiring line by growing them on media supplemented with various amino acids, vitamins and nucleic acid bases following the test system of Holliday<sup>13</sup>. Normal growth of URA401 and ILE401 (Fig. 1) could be restored by feeding 100 mg l-1 uracil and 200 mg l-1 isoleucine, respectively. Characterization of the URA401 line will be reported elsewhere.

Plants could be regenerated only from the ILE401 line. The regenerates were diploid (Fig. 2), although selection was carried out using haploid cells. Diploidy can be explained by spontaneous polyploidization known to occur frequently in cultured plant cells<sup>14</sup>. The plants, and the calli initiated from them, have an absolute requirement for isoleucine.

Table 1 The frequency of auxotrophic clones

		No. (f	requency) of

19	15	2,377	0
23	11	1,240	$2(1.6\times10^{-3})$

Haploid N. plumbaginifolia protoplasts were isolated from sterile plants<sup>21</sup>, irradiated with 60Co γ rays<sup>22</sup> and cultured in K3 medium<sup>2</sup> supplemented with 0.1% casein hydrolysate and 0.05% yeast extract. The colonies were then individually transferred onto RM medium<sup>24</sup> containing 0.1 mg l<sup>-1</sup> 1-naphthaleneacetic acid and 1.0 mg l<sup>-1</sup> benzyladenine (RMOP medium) and the same supplements as before. Calli (5-10 mm in diameter) were then halved and subcultured onto minimal (casein hydrolysate and yeast extract omitted) and supplemented RMOP medium. Auxotrophs were identified by their inability to grow on minimal medium. Dese rate was 0.042 J per kg per s. % Survival = of non-irradiated control. Plating efficiency in cultures of non-irradiated protoplasts was ~70%.

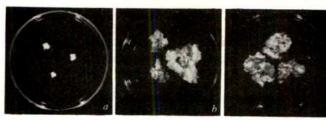

Fig. 1 Nutritional requirement of the ILE401 line. a, Minimal RMOP (see Table 1 legend) medium; b, minimal medium with 200 mg l<sup>-1</sup> L-isoleucine; c, minimal medium with 100 mg l<sup>-1</sup>  $\alpha$ aminobutyric acid. Cultures were incubated for 3 weeks in the light (2,000 lx, 16 h).

Fig. 2 Wild-type diploid N. plumbaginifolia (a) and ILE401 (b) plants. Metaphase chromosomes in root tips of an ILE401 auxotrophic plant are also shown (c).

Except for the first and last steps of their biosynthetic pathway, isoleucine and valine are synthesized by a common set of enzymes in microorganisms15 and in flowering plants16. As isoleucine alone is sufficient to restore normal growth of the ILE401 line, it may be defective in either threonine deaminase or transaminase B (Fig. 3). There was no detectable threonine deaminase activity in crude extracts of the ILE401 line, in contrast to the wild type, in which the specific activity was  $1.0 \times 10^{-3} \,\mu$ mol per min per mg protein, a value comparable with those found in other plant species 17,18. Transaminase B activity, however, was not affected in the mutant. Specific activities in the mutant and wild type were  $5.2 \times 10^{-4}$  and  $3.9\times 10^{-4}~\mu mol$  per min per mg protein, respectively. (Details of the assays of both enzymes are given in Fig. 3 legend.) The isoleucine requirement of the ILE401 line is therefore due to the absence of threonine deaminase activity. Normal functioning of the rest of the pathway was shown in growth tests in which isoleucine could be substituted with  $\alpha$ -aminobutyric acid (Fig. 1), which is converted in vivo to  $\alpha$ -ketobutyric acid<sup>19</sup>, the product of threonine deaminase. To avoid complications due to feedback inhibition by excess isoleucine20, α-aminobutyric acid was used in the test, rather than  $\alpha$ -ketobutyric acid, to provide a physiological concentration of  $\alpha$ -ketobutyric acid (thus indirectly that of isoleucine).

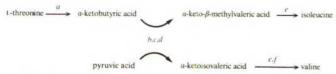

Fig. 3 The isoleucine-valine pathway. a, Threonine deaminase; b, acetohydroxy acid synthase; c, acetohydroxy acid isomeroreductase; d, dihydroxy acid dehydrase; e, transaminase B; f, transaminase C. Extracts for the enzyme assays were prepared by grinding 1 g leaf tissue in 3 ml buffer (50 mM KH<sub>2</sub>PO<sub>4</sub>, 20 mM 2-mercaptoethanol (2-ME), 2 mM EDTA, pH 8.0) and centrifuging the homogenate at 15,000g for 10 min. Threonine deaminase activity was measured at 37 °C in the presence of 62.5 mM KH<sub>2</sub>PO<sub>4</sub>, 40 mM L-threonine, 5 mM 2-ME, 0.5 mM EDTA, pH 8.0.  $\alpha$ -ketobutyric acid formed was determined by the direct method of Friedemann and Haugen<sup>25</sup>. Transaminase B activity was measured at 37 °C in the presence of 30 mM α-ketoglutaric acid, 25 mM L-isoleucine, 12.5 mM KH2PO4, 5 mM 2-ME, 0.5 mM EDTA and 0.1 mM pyridoxal phosphate, pH 8.0, using the reverse reaction. α-keto-β-methylvaleric acid formed was determined by the indirect method of Friedemann and Haugen2

The isoleucine requirement of the ILE401 line may be a result of a mutation or of epigenetic changes3. The low frequency of this phenotype, stability in culture for more than a year and expression at the plant level support the former3. Preliminary data on fusion with recessive mendelian pigment mutants indicate that isoleucine (and uracil) auxotrophies are recessive traits. A detailed genetic analysis of the ILE401 plants is in

#### Mouse IgG3 antibodies are highly protective against infection with Streptococcus pneumoniae

#### David E. Briles\*, J. Latham Claffin†, Kenneth Schroer‡ & Colynn Forman\*

\* Cellular Immunobiology Unit of the Tumor Institute, Department of Microbiology, and Comprehensive Cancer Center, University of Alabama in Birmingham, Birmingham, Alabama 35294, USA Department of Microbiology and Immunology, University of Michigan, Medical School, Ann Arbor, Michigan 48109, USA Laboratory of Pathology, National Cancer Institute, Bethesda, Maryland 20205, USA

Carbohydrate and protein antigens have been shown to elicit the bulk of their antibodies in mutually exclusive IgG subclasses in humans, mice, rats and horses<sup>1-4</sup>. In the mouse, anti-protein antibodies are primarily of the IgG1 subclass, and anti-carbohydrate antibodies are primarily of the IgG3 subclass<sup>1,2</sup>. We have now demonstrated that mouse IgG3 antibodies to the phosphocholine (PC) determinant of pneumococcal C-carbohydrate<sup>5,6</sup> and to type 3 pneumococcal polysaccharide are highly protective against experimental type 3 pneumococcal infection. This is the first demonstration that antibodies of the IgG3 subclass can protect against bacterial infection.

Previously we have demonstrated that hybridoma IgM anti-PC antibody can protect mice from infection with type 3 Streptococcus pneumoniae<sup>7</sup> strain WU2. Other data (ref. 8 and J. B. Robbins, personal communication) indicate that hybridoma anti-PC antibody can also protect against pneumococcal types 1, 4 and 6A. Much of the anti-PC antibody produced by inbred mice expresses the variable region idiotypic marker, T-15 (ref. 9). Antibodies with this idiotype have virtually identical hypervariable region sequences10, affinity for PC10 and specificity for PC analogues11. We have used protection studies with T-15positive hybridoma antibodies of different isotypes<sup>11</sup> to compare the effects of differences in constant regions without having to consider differences in specificity.

CBA/J mice were infected intravenously (i.v.) with 10° colony-forming units (CFU) of strain WU2 type 3 S. pneumoniae. This dose is 10 times the LD<sub>50</sub> (dose that kills 50% of infected mice). Passively administered IgG3 anti-PC antibody was almost 90-fold more protective against S. pneumoniae on a weight basis than IgM antibody of the same idiotype (Table 1). Similarly, IgG3 anti-type 3 antibody was almost 40 times more protective than IgM anti-type 3 antibody. Protection was not observed for IgA anti-PC antibody, IgM anti-salmonella antibody, or IgG3 anti-levan antibody. Anti-type 3 antibodies were  $\sim$ 6–15-fold more protective by weight than anti-PC antibodies. This was expected as the PC determinants, which form part of the cell wall<sup>6</sup>, should be largely buried beneath the type-specific capsule<sup>12</sup>.

We repeated these studies with  $(CBA/N \times DBA/2)F_1$  mice, which express the X-linked immunodeficiency xid 13,14 extremely low levels of natural anti-PC antibody7,15 and fail to produce anti-type 3 antibody when immunized13. These mice were infected with 150 CFU (~10×LD<sub>50</sub>) of S. pneumoniae strain WU2. IgG3 anti-PC antibodies protected xid mice ~10 times more effectively than IgM anti-PC antibodies, but IgG3 and IgM antibodies to the type 3 capsule showed roughly equal protective ability (Table 2). As with normal animals, anti-type 3 IgM was more effective than anti-PC IgM antibodies; however, IgG3 antibodies of the two specificities provided similar protection. The reasons for the different relative protective abilities of IgG3, IgM, anti-PC and anti-type 3 antibodies in normal and xid mice are unclear, but may be related to differences in immunoresponsive potential and levels of natural serum antibody of the two types of mice, or to the 4-log difference between the infectious doses used in the two studies.

Table 1 Ability of antibodies reactive with pneumococcal cell wall and capsule to protect CBA/J mice against infection with S. pneumoniae strain WU2

Hybridoma or myeloma*	Specificity	Idiotype†	Isotype†	PD <sub>50</sub> (µg per injection)‡

Mice were infected i.v. with 106 CFU of S. pneumoniae7, and protected with intraperitoneal (i.p.) injections of 0.1 ml of the indicated immunoglobulin in doses of 0.02, 0.2, 2.0, 20 or 200 µg (or 100 or 300 µg) 1 h before infection and 1 and 2 days after infection. Injection of diluent alone (0.1% fetal calf serum) was not protective. Antibody and diluent solutions were all filter-sterilized (0.22 µm) before injection. Over 80% of deaths occurred within 4 days of infection. The experiment was discontinued after 10 days.

\* Myeloma antibodies T-15, H-8 and J606 and hybridoma protein 59.6C5 were isolated by affinity chromatography<sup>11,20,25</sup>. Hybridoma proteins 16.3, CA3-1, CC4-6 (ref. 26), ST-1 (ref. 27) and PC-5-2 (a gift from John Kearney) were used as diluted ascites fluids. The amount of antibody in these fluids was quantitated by radioimmunoisotype Comparable dilutions of normal mouse serum were not pro-

The mice used here express the X-linked immunodeficiency (xid) defect of CBA/N mice, have no naturally occurring anti-PC anti-body<sup>7,15</sup> and are highly susceptible to pneumococcal infection. Mice were infected i.v. with 100 CFU of S. pneumoniae and protected as described in Table 1 legend.

Anti-PC hybridoma antibodies<sup>11</sup> were produced and isolated as

described in Table 1 legend.

The more efficient protection by IgG3 antibody in normal and xid mice is even more striking considering the fact that divalent IgG3 would be expected to have a much lower avidity than an IgM molecule for identical binding sites. IgM, which is only poorly recognized by Fc receptors 16-18, probably acts by opsonizing S. pneumoniae, using its highly efficient complement fixation<sup>19</sup>. The mechanism of IgG3-mediated killing is not so obvious. Although unaggregated IgG3 does not bind complement Cl (ref. 20), IgG3 anti-streptococcal group A carbohydrate antibody1 can apparently lyse antigen-coated red blood cells in the presence of complement<sup>21</sup>. Thus the C3b receptor of phagocytes may play a part in IgG3-mediated bactericidal activity. Fc receptors for IgG3 (ref. 22) probably contribute to the anti-pneumococcal protection observed here, as they mediate phagocytosis of sheep red blood cells (SRBC) in the presence of IgG3 anti-SRBC antibody<sup>22</sup>.

The possibility that IgG3 may mediate bactericidal activity by an antibody-dependent cellular cytotoxicity is suggested by the fact that human natural killer cells can kill bacteria23, and the recent demonstration that passive IgG3 anti-tumour antibody can protect against tumour growth far better than IgM antibody of the same specificity<sup>24</sup>.

We thank John Kearney, Max Cooper, Janet Yother, Joyce Lehmeyer, Anne Maddalena, Susan Hudak and Ann Brookshire for variously providing advice, assistance and support during these studies. This work was supported by NIH grants CA 16673, AI 15986 and AI 12533.

#### The switch region associated with immunoglobulin $C_{\mu}$ genes is DNase I hypersensitive in T lymphocytes

#### Ursula Storb, Benjamin Arp & Ronald Wilson

Department of Microbiology and Immunology, University of Washington, Seattle, Washington 98195, USA

It is not known whether the antigen-specific receptor of T lymphocytes is encoded by conventional immunoglobulin genes. Several T-cell lines, as well as thymus cells, have been found to contain aberrant IgM mRNAs, but other T-cell lines are apparently negative  $^{1-4}$ . Rearrangement of D and J gene segments which code for portions of immunoglobulin heavy (H) chain variable (V) regions has been observed in some T cells, but no complete V-D-J rearrangements, as required for H gene expression in B cells, have been found<sup>5</sup>. To investigate the chromatin structure around the  $C_{\mu}$  gene in T lymphocytes, we have probed the regions flanking the gene by mild digestion with DNase I. We report here that T-lymphocyte chromatin exhibits sites hypersensitive to DNase I in a region 5' of  $C_{\mu}$ . In B cells, this region has been proposed to be responsible for switching to downstream  $C_{\rm H}$  genes.

It has been observed in other systems that there are sites in chromatin which are hypersensitive to cleavage by DNase I<sup>6-10</sup> The location of such sites can be related to the restriction map of a specific gene. It was postulated that the hypersensitivity occurs at DNA sites which may regulate gene activity in the vicinity 6-10 To determine whether hypersensitive sites are associated with

**Fig. 1** Restriction maps of the region 5' of the  $C_{\mu}$  gene (modified from Liu *et al.* <sup>16</sup>). Deletion area <sup>15–17</sup> and switch region <sup>18–22</sup> were reported for several plasmacytomas to be involved in the deletion of sequences 5' of  $\hat{C}_{\mu}$  and the switch to other  $C_{\rm H}$  genes, respectively. Vertical arrows indicate DNase I-hypersensitive sites (the stippled arrows indicate sites in thymus visible with the  $J_{\rm H}$  probe, but indistinct with the  $C_{\mu}$  probe); \*, site that was only visible with the  $C_{\mu}$  but not with the  $J_{\rm H}$  probe—this site seems also to be hypersensitive in purified DNA (see Fig. 3). The  $J_{\rm H}$  probe is a BamHI-EcoRI fragment cloned by K. Marcu into pBR322 (ref. 15). The  $C_{\mu}$  probe is a BamHI-EcoRI (artificial Eco site) fragment from a germ-line library clone subcloned into pBR322 (R. Near, E. Selsing and U.S., unpublished results).

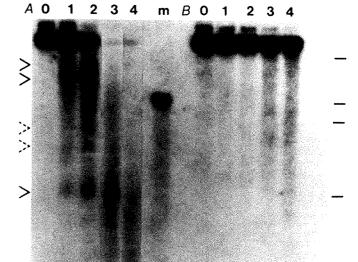

Fig. 2 Southern blots of thymus (A) and liver (B) DNAs from untreated nuclei (track 0) and nuclei treated with DNase I (tracks 1-4) to reduce gradually the size of the DNA to an average of 15-20 kb (track 4)<sup>12</sup>. The DNAs were prepared and digested with BamHI<sup>13</sup>. Southern blots<sup>28</sup> were produced and hybridized with a J<sub>H</sub> probe (see Fig. 1a). Sizing markers are indicated along the right-hand side of the gel-\(\lambda\) phage DNA cut with Aval (8.5, 6.1, 4.8 and 2.2 kb). m, Radiolabelled sizing marker due to the hybridization of the plasmid probe with the 4.6-kb phage  $\lambda$  DNA fragment. Subfragments flanked by a BamHI site and a DNase I-hypersensitive site are indicated by arrowheads. The major hybridization band is the  $J_{\rm H}$ - $C_{\mu}$  gene; the faint fragments above it are due to incomplete digestion by Bam HI.

the  $C_{\mu}$  gene in T lymphocytes, nuclei from thymus cells (>99% T lymphocytes<sup>11</sup>) and liver cells (as a control) were prepared and mildly treated with DNase I12. The range of DNase I concentrations used has been shown to digest active immunoglobulin genes without affecting inactive genes and the bulk of the DNA<sup>12</sup>. DNA was extracted from these nuclei and analysed by restriction enzyme digestion together with Southern filter hybridization to map DNase I-hypersensitive sites8. A restriction map of the  $C_{\mu}$  gene, indicating the enzyme sites used in the analyses, is shown in Fig. 1a.

Liver cells were analysed to provide controls representing a tissue in which immunoglobulin genes are not expressed 12.13. When liver DNA, extracted from untreated nuclei, was digested with BamHI and hybridized with a particular  $J_H$  probe (see Fig. 1a) a single restriction fragment of 9.8 kilobases (kb) was observed (Fig. 2B, track 0). DNAs extracted from liver nuclei treated with increasing amounts of DNase I showed the same Bam HI restriction fragment (Fig. 2B, tracks 1-4). No additional bands were observed, indicating that there are no DNase Ihypersensitive sites in this region of the liver genome.

Thymus DNA, extracted from untreated nuclei, and hybridized with the  $J_{\rm H}$  probe also showed the 9.8-kb Bam HI restriction fragment (Fig. 2A, track 0) seen with liver DNA. This supports the conclusion that in most thymus cells no DNA rearrangement has occurred in the region between  $J_{\rm H}$  and the  $C_{\mu}$ gene. In contrast to the results obtained with liver cells, however, DNase I treatment of thymus nuclei resulted in the appearance of new fragments (indicated by arrows in Fig. 2A). These subfragments must be flanked by a Bam HI site at one end and a DNase I-hypersensitive site at the other. As the  $J_{\rm H}$  probe represents the 5' end of the 9.8-kb  $J_{\rm H}$ - $C_{\mu}$  Bam HI fragment (Fig. 1a), the length of the subfragments produced by DNase I digestion indicates the distance between the BamHI site within the  $J_{\rm H}$  cluster and the DNase I-hypersensitive sites (Fig. 1b) thus allowing localization of the hypersensitive sites in the  $J_{\rm H}$ - $C_{\mu}$ map.

We have confirmed the location of DNase I-hypersensitive sites in thymus chromatin by analysis with a  $C_{\mu}$  probe (see Fig. 3 DNase I-hypersensitive sites in pure DNA. Pure thymus DNA was digested with  $16 \text{ ng ml}^{-1}$  (A) and  $32 \text{ ng ml}^{-1}$  (B) DNase I for 1 min at  $22 \,^{\circ}\text{C}$ , the reaction was stopped with EDTA, the DNA treated with proteinase K and phenol, and then precipitated with ethanol. The size of the DNAs was determined by electrophoresis in agarose gels and found to be slightly degraded to the same size as DNAs 1 and 2 (Fig. 2A) from DNase I-treated thymus nuclei. The DNAs were treated with BamHI, Southern blots 28 prepared and hybridized with the  $C_{\mu}$  probe. The arrowhead indicates a subfragment.

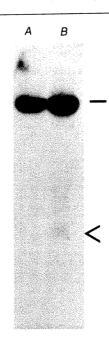

Fig. 1a). This probe represents the 3' end of the 9.8-kb  $J_{\rm H}$ - $C_{\mu}$  1a). This probe represents the 3' end of the 9.8-kb  $J_{\rm H}$ - $C_{\mu}$  BamHI fragment (see Fig. 1a). As before, liver DNA did not show any hypersensitive sites but subfragments were observed for thymus DNA (not shown). The map positions of the major hypersensitive sites in thymus DNA obtained with the  $C_{\mu}$  probe coincided with those obtained using the  $J_{\rm H}$  probe. Some subfragments apparent with the  $J_{\rm H}$  probe (stippled arrows in Figs 1b and 2A) were not discrete using the  $C_{\mu}$  probe (possibly due to a high background in the  $C_{\mu}$  blot).

The hypersensitivity of most of the sites of this genomic area is probably due to the chromatin conformation within thymocyte nuclei. One of the sites, however, may correspond to a nucleotide sequence that is preferentially digested by DNase I, because it is also observed when purified DNA is treated with DNase I (Figs 1 and 3B). It is intriguing that this site is masked in liver chromatin (not shown). The DNA sequence in this region which promotes increased DNase I susceptibility in pure DNA remains to be determined.

The large number of hypersensitive sites observed in thymus chromatin could result from the mixed population of T lymphocytes in the thymus. We have also tested a monoclonal T-cell line, BW5147 (ref. 14), for the presence of DNase I-hypersensitive sites. Mapping of hypersensitive sites in BW5147 is slightly complicated by the fact that in the AKR mouse strain from which this cell line is derived, there is a 0.8-kb deletion between the Bam site within  $C_{\mu}$  and the EcoRI site 5' of the gene (data not shown; see also ref. 15). The deletion is located somewhere within the 'deletion area' marked in Fig. 1a, where deletions in several mouse strains and cell lines have been reported<sup>15-17</sup>. There is apparently no rearrangement between the BamHI sites within  $J_H$  and  $C_\mu$  in BW5147, as the BamHI fragments are of the same size in BW5147 and AKR kidney DNA (data not shown). Using the same strategy as described above, three subfragments were observed in DNase I-digested BW5147 DNA for either the  $C_{\mu}$  (not shown) or the  $J_{\rm H}$  probe (Fig. 4, tracks 1-4). As with thymus DNA, the hypersensitive sites in BW5147 DNA map 5' of  $C_{\mu}$  (Fig. 1c). Obviously there are fewer hypersensitive sites in the DNA of the monoclonal BW5147 cells than in thymus, which may indicate that the complexity of the thymus pattern results from multiple cell populations. We are now exploring this hypothesis further by thymus cell fractionation.

The subfragments produced by DNase I digestion of thymus or BW5147 nuclei are less sharp than restriction fragments; therefore the hypersensitivity is not restricted to a single nucleotide but may span more than 100 base pairs (bp). The same observation has been made for DNase I-hypersensitive

sites associated with immunoglobulin genes in B cells (U.S. and B.A., unpublished data), and with heat-shock genes in  $Droso-phila^{10}$ . The exact location of the  $C_{\mu}$ -associated sites with respect to DNA sequence remains to be determined.

We have not found any hypersensitive sites within 12 kb 3' of the  $C_{\mu}$  gene in thymus or liver cells (data not shown). Together with the fact that liver DNA has no hypersensitive sites 5' of the  $C_{\mu}$  gene, the defined hypersensitive sites 5' of  $C_{\mu}$  in T cells suggest that this area of the genome has been preferentially activated in these cells. This behaviour is analogous to the induced DNase I-hypersensitive sites associated with active globin genes in haematopoietic cells<sup>9</sup>. 'Constitutive' DNase I hypersensitivity of sites in the vicinity of heat-shock genes of Drosophila<sup>8,10</sup> can probably be explained by the fact that these genes have some, albeit low, transcriptional activity at normal temperature<sup>18</sup>.

In B cells the central portion of the intson between  $J_{\rm H}$  and  $C_{\mu}$  has been postulated to be involved in the switching from expression of  $C_{\mu}$  to other  $C_{\rm H}$  genes, because in plasmacytomas which express  $C_{\rm H}$  genes located 3' of  $C_{\mu}$  and which have deleted  $C_{\mu}$ , a 5' portion of the  $J_{\rm H}-C_{\mu}$  intron was retained  $^{19-23}$ . In different cells different switch sites were used. Further analyses of other B cells may show that switch sites are located throughout the region between  $J_{\rm H}$  and  $C_{\mu}$ , as this entire area seems to be prone to deletions  $^{15-17}$ . We have found DNase I-hypersensitive sites in the part of the genome in B lymphocytes that expresses the  $C_{\mu}$  gene (U.S. et al., unpublished data). This may reflect the potential of these cells to switch to another  $C_{\rm H}$  gene.

It is intriguing to speculate that the hypersensitive sites in T cells may be involved in the potential of T cells to 'switch' to the expression of a downstream gene—either one of the  $C_{\rm H}$  genes active in B lymphocytes or a T-cell-specific gene. Other explanations for the hypersensitive sites in T cells must also be considered. Normal T cells and some T-cell lines produce  $C_{\mu}$ -containing RNAs<sup>1.2.4</sup>, which probably do not include correctly joined VDJ complexes (F. Alt, personal communication). Most of these  $\mu$  RNAs have their promoter 5' of  $J_{\rm H}$ , but it cannot be ruled out that some are initiated in the switch region (F. Alt, personal communication). Thus, it is unknown whether any or all of the  $C_{\mu}$ -associated DNase I-hypersensitive sites of T cells mark transcriptional promoters.

Finally, it is possible that the hypersensitive sites in T cells are not directly correlated with any function. First, they may simply

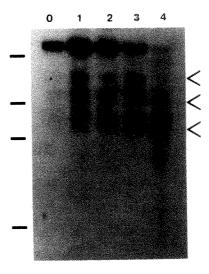

Fig. 4 Southern blot of BW5147 DNA from untreated nuclei (0) and nuclei treated with DNase I (tracks 1-4) to reduce gradually the size of the DNA to an average of 20 kb (ref. 12). BamHI digestion was followed by Southern blotting 13 and hybridization with J<sub>H</sub> probe. Sizing markers indicated along the left-hand margin are λ phage DNA cut with AvaI (see Fig. 2 legend). Subfragments flanked by a BamHI site and a DNase I-hypersensitive site are indicated by arrowheads.

reflect the origin of T cells from a lymphoid precursor common to B and T cells. However, in this context it is surprising that B cells show only one hypersensitive site in this region (U.S. and B.A., unpublished results) compared with at least three in T cells. Second, these sites may have become activated in the course of the activation of some other T-cell-specific gene in the vicinity. This would be analogous to the finding of aberrant rearrangements of immunoglobulin genes in B lymphocytes

#### Introduction of a rabbit $\beta$ -globin gene into the mouse germ line

#### Franklin Costantini & Elizabeth Lacv

Department of Zoology, University of Oxford, South Parks Road, Oxford, OX1 3PS, UK

The introduction of cloned foreign genes into cultured mammalian cells<sup>1-7</sup> has been used to identify DNA sequences required for correct transcription in vivo<sup>8-10</sup>. It is not clear, however, to what extent these systems will be useful for an analysis of the sequences necessary for tissue-specific gene expression. A more appropriate approach for such an analysis might be the production of mice that contain a cloned foreign gene in all their cells, throughout development. This could be accomplished by the transfer of a cloned gene into germ-line cells, and the subsequent transmission of that gene to offspring. Previously, SV40 DNA sequences<sup>11</sup> and a cloned HSV-1 thymidine kinase gene<sup>12</sup> have been introduced into somatic tissues of mice by microinjection of the DNAs into blastocysts11 or eggs<sup>12</sup>, but germ-line transmission of these sequences has not been demonstrated. The only foreign DNA sequences which have been transferred into and transmitted by the mouse germline have been exogenous Moloney leukaemia virus genomes introduced by viral infection of early embryos<sup>13</sup>. We now report the introduction of a cloned rabbit DNA fragment containing the adult  $\beta$ -globin gene into the germ-line of mice. We have analysed 24 mice derived from eggs microinjected with this DNA. Nine mice contain the rabbit  $\beta$ -globin gene in liver DNA. and at least four males from this group transmit the gene to a fraction of their progeny.

Fertilized eggs were recovered 3-7 h before first cleavage from (C57BL)6×CBA/H)F1 female mice that had been mated to  $(C57BL/6 \times CBA/H)F_1$  males, and one pronucleus was injected with DNA, using a glass micropipette<sup>12</sup>. The DNA was prepared from a recombinant bacteriophage, λCH4A.RβG2  $(\lambda R\beta G2)$ , which contains the rabbit adult  $\beta$ -globin gene,  $\beta 1$ , and a  $\beta$ -like pseudogene,  $\Psi\beta2$ , in a 19-kilobase pair (kbp) chromosomal DNA fragment<sup>14-16</sup> (see Fig. 1). Most of the  $\lambda R\beta G2$  DNA was in the form of linear monomers but a small fraction (10-20%) consisted of multimers, noncovalently joined by the cohesive ends of  $\lambda$  DNA. Approximately 1 pl of DNA solution, at concentrations ranging from 5 to 50 µg ml<sup>-1</sup>, corresponding to 100-1,000 ARBG2 molecules, was injected into a

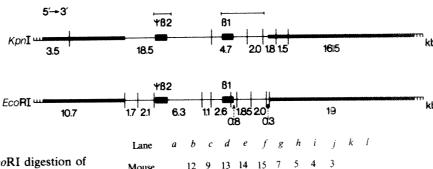

pronucleus. Eggs that survived injection (50%) were transferred to the oviducts of pseudo-pregnant (C57BL/6×CBA/H)F, females<sup>17</sup>, and 15% of them developed to term, yielding a total of 51 live-born mice. Partial hepatectomies were performed on 24 of the mice at 6-8 weeks of age. Total liver DNA was extracted, digested with the restriction endonuclease KpnI and screened for rabbit  $\beta$ -globin sequences by Southern blot hybridization<sup>18</sup>

Figure 2 shows the results for the first 18 mice. Eight of these mice contain sequences in their liver DNA which hybridize to probes for the rabbit  $\beta$ -globin genes,  $\beta 1$  and  $\Psi \beta 2$ . The most intensely hybridizing bands correspond in size to three  $\lambda R\beta G2$ KpnI fragments homologous to the probes (18.5, 4.7 and 2.0 kbp; see Fig. 1). Of six more mice screened (data not shown), one also contains the same  $\lambda R\beta G2$  KpnI fragments. The average number of copies of the rabbit  $\beta$ -globin gene per liver cell in each of the positive mice may be estimated from the intensities of hybridization relative to known amounts of Kpn Idigested  $\lambda R\beta G2$  DNA in parallel lanes. Mice 40 (not shown) and 7 contain 1 or 2 copies, mice 3, 4, 13, 37 and 38, 5-10 copies, and mice 9 and 23, more than 20 copies. Although the sample size is small, there is no obvious correlation between the concentration of the injected DNA and the presence or copy number of  $\lambda R\beta G2$  sequences in these mice.

To determine whether the  $\lambda R\beta G2$  sequences are transmitted through the male germ line, we mated four male mice containing the rabbit sequences with normal CBA/H females. Total DNA was prepared from several whole newborn progeny, restricted with EcoRI and screened for  $\lambda R\beta G2$  sequences using  $^{32}$ P-labelled  $\lambda$ R $\beta$ G2 DNA as a probe. As shown in Fig. 3, all four mice transmitted  $\lambda R\beta G2$  sequences to a fraction of their progeny. These fractions are: one out of four progeny for mice 4 and 23, two out of four for mouse 7, and two out of six for mouse 13. Progeny from the other five positive mice have not yet been analysed. For at least two of the mice transmitting rabbit  $\beta$ globin sequences (mice 4 and 7), the intensity of hybridization to  $\lambda R\beta G2$  is significantly greater for the progeny DNAs than for the parent liver DNAs. One likely explanation is that these mice are chimaeric, and only a fraction of their liver cells contain the  $\lambda R\beta G2$  sequences, whereas all the cells of their progeny contain them. If this is so, the apparent number of copies in liver DNA may underestimate the true copy number in those cells that do contain  $\lambda R\beta G2$  sequences. A further analysis of the tissue distributions and transmission patterns of the rabbit DNA sequences should distinguish between this and alternative explanations.

The results shown in Fig. 3 also provide information about the structure of the  $\lambda R\beta G2$  sequences present in the cells of the

Fig. 1 Restriction maps of  $\lambda R\beta G2$  DNA.  $\lambda R\beta G2$ consists of a 19-kbp rabbit chromosomal DNA fragment (thin line) cloned in a bacteriophage  $\lambda$ -vector (thick lines)<sup>14,24</sup>.  $\beta$ 1 and  $\Psi\beta$ 2 (solid boxes) are, respectively, the adult  $\beta$ -globin gene and a  $\beta$ -like pseudogene<sup>15,16</sup>. The symbols  $\sqcup \sqcup$  and  $\top \sqcap$  represent the single-stranded cohesive ends of the & vector DNA. DNA was isolated from purified phage particles<sup>24</sup> and dissolved in 10 mM Tris pH 7.4, 0.1 mM EDTA for injection into mouse eggs. The bars drawn above the KpnI restriction map depict the regions of ARBG2 that are contained in the probes used in Fig. 2.

Mouse

positive mice and their progeny. Whereas EcoRI digestion of linear  $\lambda R\beta G2$  DNA generates fragments of 19 and 10.7 kbp, corresponding to the two arms of the  $\lambda CH4A$  vector (see Fig. 1), the mouse DNAs do not contain the 19- and 10.7-kbp fragments; but in every case, a 30-kb band equal in length to the sum of the two & vector arms is seen. In addition, all the bands expected from EcoRI digestion of the rabbit DNA insert in ARBG2 are detected in the DNAs of the positive mice. Together with the results of Fig. 2, these data suggest that the parent liver and progeny DNAs contain intact copies of  $\lambda R\beta G2$ . The 30-kbp EcoRI band in the mouse DNAs is not sensitive to denaturation in conditions that melt the cohesive ends of λ DNA<sup>19</sup> (65 °C, 0.01 M Tris, pH 8), which indicates that the ARBG2 copies exist as either circular or multimeric molecules whose cohesive ends have been covalently joined in the mouse cells.

One possible interpretation of these data is that the  $\lambda R\beta G2$ sequences are integrated into mouse chromosomes in tandem arrays. In this case, the 30-kbp EcoRI fragment in the mouse DNAs would be derived from the joining of the left and right ends of adjacent  $\lambda R\beta G2$  molecules. Linear DNA molecules are rapidly ligated into high molecular weight concatemers following injection into fertilized frog eggs<sup>20</sup>, and DNA-mediated transformation of mammalian cells by the calcium phosphate precipitation method is believed to involve the formation of large DNA consequences before chromosome integration 21,22 large DNA concatemers before chromosome integration Possibly, microinjected  $\lambda R\beta G2$  DNA integrates by a similar mechanism in mouse eggs or early embryos. This interpretation predicts that new EcoRI fragments which hybridize to \(\lambda \text{R} \beta \text{G2}\) should be generated at the ends of each integrated array of ARBG2 molecules. Most of the positive mouse DNAs do, in fact, show one or more new, fainter EcoRI bands in addition to the strong bands that are due to multiple copies of  $\lambda R\beta G2$ . These are visible in several of the lanes of Fig. 3. Mouse 13, for example, shows a new EcoRI fragment about 12 kbp in length (panel e, lane B) which is inherited by both of its positive progeny (panel d, lanes B and F). Mice 7 and 23 (panels  $\hat{b}$  and c) also show new EcoRI fragments which are transmitted to their progeny. The observation that these new bands are inherited is consistent with the prediction that the bands represent junction fragments generated at sites of chromosomal integration. As no more than two or three new bands are seen in either KpnI or EcoRI digests of the positive DNAs, it is unlikely that the mice could contain many individually integrated copies of  $\lambda R\beta G2$ . Although our data support a model of chromosomal integration, they do not formally eliminate other interpretations, such as the autonomous replication and germ-line transmission of free  $\lambda R\beta G2$  circles. We are now attempting to detect integration of the rabbit DNA sequences by in situ hybridization to metaphase chromosomes<sup>22</sup>

In conclusion, we have demonstrated that a large eukaryotic DNA fragment can be introduced at a high frequency into mouse tissues, in the absence of selection, and transmitted through the germ line. Therefore, many strains of mice can now be produced that carry the adult rabbit  $\beta$ -globin gene and its flanking sequences in all their cells. With such strains of mice it will be possible to examine the expression of the rabbit  $\beta$ -globin gene and to investigate whether expression is restricted to specific tissues and/or developmental stages. If the rabbit sequences are integrated into mouse chromosomes, presumably different strains will contain the rabbit genes at different

Fig. 2 Detection of λRβG2 sequences in mouse liver DNAs. Liver tissue samples (0.2-0.4 g) were surgically removed from 6-8-week-old mice, frozen in liquid nitrogen and stored at  $-80\,^{\circ}\text{C}$ . High molecular weight DNA was extracted by the method of Blin and Stafford25 with the following modifications. Powdered frozen tissue was suspended by pipetting in 0.1 M EDTA, 0.05 M Tris pH 8 and subsequently brought to 0.5 M NaCl, 0.5% (v/v) Sarkosyl and 250  $\mu$ g ml<sup>-1</sup> proteinase K. Before the final dialysis step, the DNA was precipitated with ethanol. Yieldsranged from 200 to 800  $\mu$ g of DNA from each liver sample. 10 µg of each DNA was digested with KpnI (New England Biolabs), fractionated by electrophoresis on 0.75% agarose gels and transferred to nitrocellulose filters 18 following cleavage by partial depurination26. The hybridization probe was a mixture of two plasmids, one containing the  $\beta$ 1 gene on a 5.6-kbp Psd fragment and the other containing the  $\Psi\beta2$  gene on a 2.3-kbp EcoRI-BgIII fragment. The regions of  $\lambda R\beta G2$ corresponding to these probes are shown in Fig. 1. Probe DNA was labelled with  $^{32}$ P by nick translation<sup>27</sup> to a specific activity of  $4\times10^8$  d.p.m. per  $\mu$ g and used at a concentration of 7 ng ml $^{-1}$ . Filters were prehybridized for 6 h and hybridized for 18 h essentially as described by Wahl et al. hybridization the filters were washed for 12 h at 66 °C in 2 × SSC, 0.5% SDS. 0.01 M sodium phosphate pH 6.8, 0.05% sodium pyrophosphate and 0.001 M EDTA, and then for 1 h at 55 °C in a 10-fold dilution of the same buffer. In these conditions, no cross-hybridization between the rabbit  $\beta$ globin probe and normal mouse DNA is detected. Lanes a and m, molecular weight markers. Lanes b-j and n-v, Kpnl-digested liver DNA from 18 mice derived from injected eggs. Lanes k and w, 80 pg of Kpnl-digested  $\lambda R\beta G2$ DNA plus 10 µg of salmon sperm DNA. Lanes I and x, 800 pg of Kpnldigested  $\lambda R\beta G2$  DNA plus 10  $\mu g$  of salmon sperm DNA. These amounts correspond to 1 and 10 copies of  $\lambda R\beta G2$  per diploid genome in 10  $\mu g$  of mouse DNA, and the limit of detection on the autoradiographs was 0.1-0.2 copies per diploid genome. The 18.5-, 4.7- and 2.0-kbp fragments of  $\lambda R\beta G2$  hybridize strongly to the probe whereas the 1.8-kbp fragment hybridizes weakly. Other bands visible in the digest of  $\lambda R\beta G2$  (lanes l and x) are partial digestion products

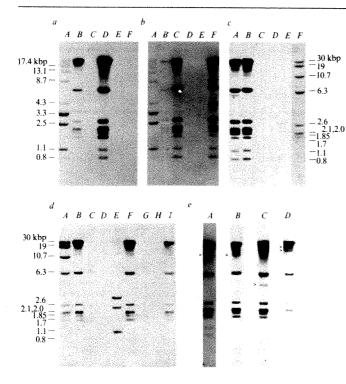

Fig. 3 Transmission of  $\lambda R\beta G2$  sequences through the male germ line. Four male mice containing  $\lambda R\beta G2$  sequences in liver DNA were mated to normal CBA/H females and total DNA was isolated from their whole newborn progeny. Liver DNAs from the four males (10 µg) and total DNAs from broken their progeny (10  $\mu$ g) were digested with EcoRI (Boehringer), fractionated on 0.5% agarose gels and blotted. Filters were hybridized to  $^{32}$ P-labelled  $\lambda R\beta G2$  DNA (2-4×10<sup>8</sup> d.p.m. per  $\mu g$ ; 10 ng ml<sup>-1</sup>). Panel a: lane A, molecular weight markers whose sizes are indicated on the left; lane B, liver DNA from mouse 4; lanes C-F, total DNAs from four progeny of mouse 4. Panel b: lane A, molecular weight markers; lane B, liver DNA from mouse 7; lanes C-F, total DNAs from four progeny of mouse 7. The DNA sample in lane F is incompletely digested by EcoRI. Panel c: lane A, liver DNA from mouse 23; lanes B-E, total DNAs from four progeny of mouse 23; lane F, a mixture of linear monomers and concatemers of ARBG2 digested with EcoRI. The 19- and 10.7 kbp fragments are the λ vector arms of monomeric linear  $\lambda R\beta G2$  (see Fig. 1). The 30-kbp fragment derives from concatemers and consists of the 19- and 10.7-kbp fragments joined by the  $\lambda$  cohesive ends. The smaller fragments are the EcoRI digestion products of the rabbit DNA insert in  $\lambda R\beta G2$ . Panel d: lane A, same as lane F of panel c; lanes B-D and F-H, total DNAs from six progeny of mouse 13; lane E, molecular weight markers; lane I, liver DNA from mouse 13. Panel e: EcoRI-digested liver DNAs from four of the positive mice hybridized to  $^{32}P$ -labelled  $\lambda R\beta G2$ DNA. Each lane is exposed to show one or more new, faint bands not characteristic of  $\lambda R\beta G2$ . Lane A (a longer exposure of lane I, panel d) contains liver DNA from mouse 13 and shows a faint band at which is also visible in two of the progeny of mouse 13 (lanes B and F, panel d). Lane B contains liver DNA from mouse 7 and shows a faint band of  $\sim$ 13 kbp, which is visible in at least one of the progeny of mouse 7 (lane C, panel b). Lane C contains liver DNA from mouse 37 which shows a new band at ~4.5 kbp. Lane D contains liver DNA from mouse 38 which shows two new bands at roughly 15 and 20 kbp. Progeny from mice 37 and 38 have not been analysed.

chromosomal locations. This will allow us to investigate how the host chromosomal environment influences the expression of a foreign gene<sup>2</sup>

Since the submission of our manuscript, chromosomal integration of the  $\lambda R\beta G2$  sequences in mouse 23 has been demonstrated by in situ hybridization to metaphase chromosome spreads prepared from peripheral blood. The probe was 125 I-labelled AR &G2 DNA, and hybridization was performed as described by Robins et al.22. In every metaphase spread examined (19), intense labelling was observed at a site in the middle of one homologue of chromosome 1. This indicates that most if not all of the copies of  $\lambda B\beta G2$  in this mouse are integrated into chromosome 1.

We thank Chris Graham for advice and encouragement throughout this project, Jon Gordon and Frank Ruddle for advice on microinjection techniques and Ivor Mason for technical assistance. F.C. and E.L. were recipients of postdoctoral fellowships from the NIH (HD05893-02) and the American Cancer Society (grant PF-1759), respectively. This research was supported by a grant to C. F. Graham from the Cancer Research Campaign.

#### Transcriptional regulation of the prolactin gene by ergocryptine and cyclic AMP

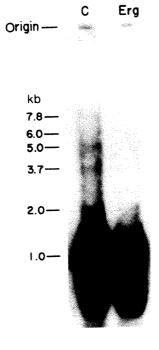

#### Richard A. Maurer

Department of Physiology and Biophysics, University of Iowa, Iowa City, Iowa 52242, USA

A large body of evidence suggests that the synthesis<sup>1,2</sup> and secretion3-7 of the pituitary hormone prolactin is inhibited by the hypothalamic hormone dopamine. The finding that dopamine inhibits adenylate cyclase activity of rat pituitary human prolactin-secreting adenoma' suggests that the dopaminergic inhibition of prolactin synthesis may be mediated by decreased levels of cyclic AMP. Recently, the dopaminergic inhibition of prolactin synthesis has been shown to involve decreased concentrations of prolactin mRNA<sup>2,10</sup>. Furthermore, monobutyryl cyclic AMP increases prolactin mRNA levels in pituitary cells treated with the potent dopaminergic agonist ergocryptine11. Such changes in prolactin mRNA levels could involve transcriptional or post-transcriptional events. Here we report that treatment of pituitary cells with ergocryptine leads to rapid inhibition of prolactin gene transcription and that addition of monobutyryl cyclic AMP to ergocryptine-pretreated cells results in a rapid stimulation of prolactin gene transcription.

We first examined the effect of ergocryptine on the levels of nuclear precursors of prolactin mRNA. Previous work has demonstrated the presence of large, potential precursors of prolactin mRNA in pituitary cell nuclei<sup>12</sup>, the largest of these being 7.0 kilobases (kb); the mature prolactin mRNA is 1.0 kb.

Fig. 1 The effect of ergocryptine on possible nuclear precursors of prolactin mRNA. Dispersed pituitary cells were prepared, initially plated in serum-containing medium and then maintained in serum-free Dulbecco's modified Eagle's medium as described previously2, except that the cells were plated in large, 15-cm diameter tissue culture dishes. After 2 days in serumfree medium, half the cultures were treated with 10 nM ergocryptine (Erg) while the controls (C) received only saline. After 24 h, the cells were scraped from the plate in phosphate-buffered saline (PBS) and collected by low-speed centrifugation. The cell pellet was homogenized in 0.25 M sucrose, 20 mM Tris pH 7.9, 5 mM MgCl<sub>2</sub>, 0.1% Triton X-100 using 12 strokes of the tight pestle of a Dounce homogenizer and 2.0 ml of the homogenate were then layered over a sucrose cushion consisting of 1.5 ml of 0.5 M sucrose, 20 mM Tris pH 7.9. 5 mM MgCl<sub>2</sub> and 1.0 ml of 0.3 M sucrose in the same buffer. The sample was then centrifuged at 1,000g for 10 min. The solution above the sucrose cushion was aspirated, the sides of the tube washed with water and the remaining solution decanted.

The nuclear pellet was resuspended in homogenization buffer and centrifuged through sucrose cushions once more. The nuclear pellet was then dissolved in 7 M guanidine HCl, 20 mM Tris pH 7.4, 1 mM EDTA, 1% Sarkosyl using a Dounce homogenizer. The homogenate was layered over 1.5 ml of 5.7 M CsCl, 0.1 M EDTA and centrifuged at 33,000 r.p.m. at 20 °C for 16 h in the SW50.1 rotor. The RNA which pelleted through the CsCl cushion was dissolved in sterile water and precipitated by addition of 0.1 volume 3 M sodium acetate pH 7 and 2.5 volumes of ethanol. Nuclear RNA (8.8  $\mu$ g) from control and ergocryptine-treated cells was denatured by treatment with glyoxal and electrophoresed on a 1.25% agarose gel. The RNA was then transferred to nitrocellulose by blotting as described elsewhere<sup>27</sup>. Prehybridization and hybridization conditions were as described elsewhere<sup>27</sup>. The hybridization probe was a recombinant DNA plasmid, pPRL-2, labelled with <sup>32</sup>P by nick translation <sup>15</sup> to a specific activity of  $2 \times 10^8$  c.p.m. per  $\mu$ g. After hybridization the filter was washed as described elsewhere<sup>27</sup> then exposed to X-ray film in the presence of an intensifying screen. Numbers indicate the sizes of the RNA species in kb.

Hoffman et al.13 have recently detected even larger possible precursors of prolactin mRNA. If the dopaminergic inhibition of prolactin mRNA levels involves effects on the transcription of the prolactin gene, then the concentration of the prolactin mRNA nuclear precursors should decrease. Thus we determined the effect of ergocryptine on prolactin mRNA precursors using techniques similar to those used previously12. Nuclear RNA isolated from ergocryptine-treated and control pituitary cells was denatured with glyoxal, electrophoresed on an agarose gel, then transferred to nitrocellulose. To identify prolactin mRNA species, the filter-immobilized RNA was hybridized to a radiolabelled recombinant DNA plasmid containing the complete prolactin coding sequence<sup>14</sup>. This plasmid, pPRL-2, was labelled *in vitro* with <sup>32</sup>P by nick translation<sup>15</sup>. Using this procedure, multiple, large RNA species containing prolactin sequences were detected in nuclear RNA from control cells (Fig. 1). In ergocryptine-treated cells, there was a considerable decrease in the hybridization of labelled pPRL-2 to all the high-molecular weight species of prolactin mRNA, which suggests that ergocryptine greatly reduced the concentration of prolactin mRNA precursors in these cells. These results suggest that ergocryptine may inhibit transcription of the prolactin gene. However, the RNA transfer technique has at least two limitations for analysis of gene regulation: (1) it is difficult to obtain quantitative information from the procedure-partly due to the fact that different transfers may have different efficiencies and the RNA bands may be better resolved in some transfers than others; (2) the technique only provides information on the concentration of various prolactin mRNA species; it does not rigorously demonstrate changes in synthesis. Therefore, further experiments were performed in which the de novo synthesis of prolactin mRNA sequences was quantitated.

Isolated nuclei provide a useful system for the analysis of transcriptional regulation. In most nuclei transcription systems, RNA synthesis is due primarily to elongation of RNA chains with very little initiation of new RNA chain synthesis 16.17. Therefore, when nuclei are allowed to continue RNA synthesis in vitro, the RNA produced should accurately reflect RNA

Monolayer cultures of dispersed pituitary cells were prepared, plated in serum containing medium and then maintained in serum-free Dulbecco's modified Eagle's medium as described in Fig. 1 legend. Cells were treated with 10 nM ergocryptine, 10 nM ergocryptine + 0.5 mM monobutyryl cyclic AMP (Bt-cAMP), or saline (controls) for 24 h then the cells were scraped from the plate in PBS and collected by centrifugation at 500g for 10 min. Isolated nuclei were prepared from the cells as described in Fig. 1 legend, used to synthesize <sup>32</sup>P-RNA, and prolactin mRNA synthesis determined as described in Table 1 legend.

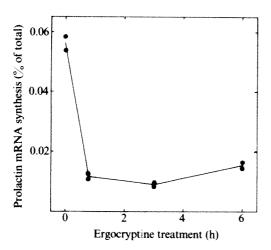

Fig. 2 Time course of ergocryptine effects on prolactin mRNA synthesis. Dispersed pituitary cells from female rats were cultured as described in Fig. 1 legend. After 2 days in serum-free medium, the cells were treated for the time indicated with 10 nM ergocryptine, then scraped from the plates and nuclei prepared. The isolated nuclei were allowed to synthesize RNA and prolactin mRNA synthesis was determined as in Table 1 legend.  $^{32}\text{P-RNA}$  input into each hybridization was  $7{-}10\times10^6$  c.p.m. Points indicate values obtained from duplicate independent assays from the same experiment; the line connects average values.

synthesis which occurred in vivo. The synthesis of a particular RNA can then be determined by hybridization of the RNA to filter-immobilized recombinant DNA containing the sequence of interest. Nonspecific hybridization was determined using filters containing the wild-type plasmid DNA and this value was subtracted from the radioactivity hybridized to filters containing prolactin recombinant DNA. The rate of prolactin mRNA synthesis was calculated by dividing the radioactivity in specific prolactin sequences by the input radioactivity. This procedure was used to examine prolactin mRNA synthesis in pituitary cell and HTC rat hepatoma cell nuclei (Table 1). Prolactin mRNA synthesis was reduced to near background levels by a concentration of  $\alpha$ -amanitin  $(1 \mu g m l^{-1})$  which should inhibit RNA polymerase II (refs 18, 19). Total RNA synthesis was inhibited -40% by this concentration of  $\alpha$ -amanitin. There was no detectable synthesis of prolactin mRNA sequences in nuclei from the HTC cell line. Addition of competitor prolactin mRNA to the hybridization mixture resulted in similar reductions in the hybridization of <sup>32</sup>P-RNA transcripts and prolactin <sup>3</sup>H-cRNA. This demonstrates that the labelled prolactin transcripts result from asymmetric transcription of the sense strand of the prolactin gene. Thus, the synthesis of prolactin mRNA sequences by

isolated nuclei is tissue-specific, asymmetric and mediated by RNA polymerase II.

Treatment of pituitary cells with ergocryptine for 24 h decreased the synthesis of prolactin mRNA sequences by isolated nuclei (Table 2). In one experiment prolactin gene transcription was reduced nearly 10-fold and in a second experiment there was a >4-fold reduction in prolactin mRNA synthesis. Analysis of the time course of the effects of ergocryptine demonstrated that the inhibition of prolactin gene transcription was rapid (Fig. 2). After 45 min of ergocryptine treatment, the earliest time point examined, prolactin mRNA synthesis was reduced almost fivefold and no greater reduction was detected after 3 or 6 h of treatment.

Simultaneous addition of 0.5 mM monobutyryl cyclic AMP partially blocked the ability of ergocryptine to inhibit transcription of the prolactin gene (Table 2). Previous studies have shown that cyclic AMP derivatives have little or no effect by themselves, but that they effectively reverse the dopaminergic inhibition of prolactin synthesis and hence prolactin mRNA levels<sup>11</sup>. Therefore, the effect of monobutyryl cyclic AMP was tested only in cells treated with ergocryptine rather than testing the effect of the cyclic AMP derivative alone. Analysis of the

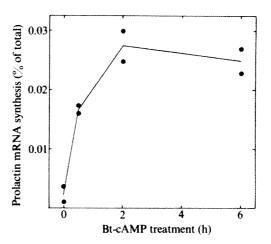

Fig. 3 Time course of monobutyryl cyclic AMP effects on prolactin mRNA synthesis in ergocryptine-pretreated cells. Cultured pituitary cells were prepared as in Fig. 1 legend and after 2 days in serum-free medium they were treated with 10 nM ergocryptine for 24 h. Then 1.0 mM monobutyryl cyclic AMP (Bt-cAMP) was added for the time indicated (the 0 time point received no cyclic AMP) and nuclei prepared from the cells. Transcription and analysis of prolactin mRNA synthesis were as described in Table 1 legend. <sup>32</sup>P-RNA input into each hybridization was 6-8 × 10<sup>6</sup> c.p.m. Points indicate values obtained from duplicate determinations; the line connects average values.

time course of monobutyryl cyclic AMP effects in ergocryptinepretreated cells revealed a rapid stimulation of prolactin gene transcription (Fig. 3). After 30 min, prolactin mRNA synthesis was stimulated about eightfold. Apparently maximal stimulation of >10-fold increases in prolactin gene transcription were detected after 2 and 6 h of cyclic AMP treatment.

The time course and magnitude of ergocryptine effects suggest that the principal mechanism involved in the dopaminergic inhibition of prolactin mRNA accumulation is the inhibition of prolactin gene transcription. Ergocryptine induced a 4- to 10-fold reduction in prolactin gene transcription, which is similar in magnitude to its effects on prolactin synthesis and prolactin mRNA levels2. This inhibition of prolactin transcription is rapid and clearly precedes the changes in prolactin mRNA levels, which decrease much more slowly2.

It seems likely that the dopaminergic regulation of prolactin gene transcription is mediated by cyclic AMP. Previous studies have shown that dopamine agonists inhibit pituitary adenylate cyclase<sup>8.9</sup>, decrease pituitary cyclic AMP levels<sup>11,20,21</sup> and inhibit prolactin synthesis and mRNA accumulation<sup>2,10</sup>. Furthermore, cyclic AMP stimulates prolactin synthesis and prolactin mRNA accumulation in ergocryptine-treated cells11. These studies suggest that in the absence of dopamine, pituitary cells contain high levels of cyclic AMP which stimulate prolactin mRNA accumulation. Thus, dopaminergic treatment decreases cyclic AMP levels, leading to decreases in prolactin mRNA concentrations. The finding that addition of monobutyryl cyclic AMP to ergocryptine-treated cells results in a rapid stimulation of prolactin mRNA synthesis demonstrates that the ability of cyclic AMP to alter prolactin mRNA levels involves effects at the transcriptional level.

Recently, cyclic AMP has been shown to alter the transcription of a gene for a developmentally regulated protein of Dictyostelium discoideum<sup>22</sup>. The finding that cyclic AMP affects transcription of the prolactin gene demonstrates that it can also affect gene transcription in higher eukaryotes. This is particularly interesting in view of the effects of cyclic AMP on prokaryotes in regulating the transcription of specific genes<sup>23</sup>. In Escherichia coli, a cyclic AMP binding protein interacts with specific promoter sites to alter gene transcription. The dopaminergic regulation of prolactin gene transcription may provide a useful model system for further analysis of the role of cyclic AMP in regulating the transcription of eukaryotic genes.

This work was supported by NIH grant AM 21803 and Endocrine Core Center grant AM 25295. I thank Dr P. A. Weil for helpful discussions concerning transcription systems and B. Maurer for technical assistance and aid in preparing the manuscript.

#### Effects of dexamethasone and cortisone with X-ray irradiation on transformation of C3H 10T<sup>1</sup>/<sub>2</sub> cells

#### Ann R. Kennedy\* & Ralph R. Weichselbaum†

 \* Laboratory of Radiobiology, Department of Physiology, Harvard School of Public Health, Boston, Massachusetts 02115, USA † Joint Center for Radiation Therapy, Harvard Medical School, Boston, Massachusetts 02115, USA

Hormones can influence carcinogenesis in experimental animals1 and it has been proposed that sex hormones may act like tumour-promoting agents in their ability to enhance the incidence of cancer<sup>2</sup>. On the other hand, it has been observed that the glucocorticoid hormone, dexamethasone, suppresses the enhancement of chemical carcinogenesis in vivo<sup>2</sup> and of transformation in vitro3 brought about by exposure to the tumour-promoting agent, 12-O-tetradecanoyl-phorbol-13acetate (TPA). We report here that the glucocorticoid hormones, cortisone and dexamethasone, do not suppress radiation transformation of C3H  $10T_2^1$  cells in vitro. Indeed, cortisone induces transformation of cells by itself, and increases the yield of radiation-induced transformants in a synergistic fashion.

We used a cell line<sup>4,5</sup> derived from C3H mouse embryos (10T<sub>2</sub>, clone 8) adapted for studies of radiation transformation<sup>6-9</sup>. For the transformation assays, cells were exposed to either 0 or 400 rad of X rays, with or without  $10^{-7}$  M dexamethasone or cortisone (determined in separate experiments to be the highest non-toxic dose). Dexamethasone or cortisone (Sigma) was added to the cultures immediately after irradiation and subsequently added at each medium change for the entire 6-8-week transformation assay.

The assay has been described in detail elsewhere and involves identifying and scoring dense foci of cells in a culture dish. Briefly, type 1 foci represent areas of abnormally dense growth, but with no other deviations from normal cell morphology; cells from these foci are not tumorigenic in mice<sup>6</sup>. Type 2 foci are large and the cells are extensively piled up and moderately stellate in appearance<sup>6</sup>; type 2 cells are tumorigenic in 60-75% of inoculated mice<sup>6</sup>. Type 3 foci are large and contain cells that are very densely piled up and which are highly stellate and show marked criss-crossing and swirling at the border of the focus. Type 3 cells are tumorigenic in 80-100% of inoculated mice<sup>6</sup>. Types 2 and 3 foci were scored as transformants, but tabulated separately.

The results (Table 1) show that cortisone  $(10^{-7} \text{ M})$  by itself is capable of inducing transformation in C3H 10T½ cells, whereas dexamethasone (10<sup>-7</sup> M) is not. When cortisone treatment followed X-ray exposure, the yield of transformants was significantly higher than expected for either agent alone or for the expected additive effect of both agents (using  $\chi^2$  analysis with Yates' continuity correction). Thus, for cells exposed to both cortisone and X rays, there seems to be a synergistic response for the induction of malignant transformation. When radiation exposure was combined with dexamethasone treatment, there was also a higher observed yield of transformants

**Table 1** Effect of cortisone  $(10^{-7} \text{ M})$  and dexamethasone  $(10^{-7} \text{ M})$  on transformation of C3H  $10T_2^1$  cells

Details of experimental techniques used in radiation transformation experiments on  $10T_2^1$  cells have been described elsewhere 6-9. Stock cultures were maintained in 60-mm Petri dishes and were passaged by subculturing at a 1:20 dilution every 7 days. The cells used were in passages 9-14. These were grown in a humidified 5% CO<sub>2</sub> atmosphere at 37 °C in Eagle's basal medium supplemented with 10% heat-inactivated fetal calf serum and antibiotics. Cells were irradiated 24 h after seeding. Plating efficiencies were determined from three plates seeded with a cell density one-fifth that of the plates used for the transformation assay; these cultures were terminated at 10 days. The various toxicities were considered in the design of the experiments. All dishes used for the transformation assay contained ~300 viable cells per dish. Types 2 and 3 foci were scored as transformants, as described by Terzaghi and Little<sup>6</sup>. We have not quantitated our results in terms of 'transformation frequency per surviving cell' because this method should not be used for the malignant transformation of C3H  $10T_2^1$  cells, as described in detail elsewhere<sup>8.9</sup>.

Chi-square analysis (with Yates' continuity correction) of the data for the fraction of dishes used which contained types 2 and 3 foci gave the following results: group a against b, P < 0.001; a against c, P < 0.01; c against e, P < 0.001; b against e, P < 0P < 0.05; b + d against f, P > 0.05. In addition, P > 0.05 was obtained for the data from the three treatment groups when the fraction of dishes containing only type 3 foci was compared. Fisher's exact test (types 2 and 3 foci): a against d, P > 0.05.

than expected for an additive effect of the treatments. However, the yield of transformants after X-ray irradiation and dexamethasone treatment was not significantly greater than the yield of transformants observed for radiation alone or for the expected additive effect of the combined treatments. As similar results were obtained in four separate experiments, these data were pooled (see Table 1).

Mondal and Heidelberger<sup>3</sup> reported that dexamethasone suppressed TPA-enhanced transformation in vitro, and similar results have been reported for TPA-enhanced chemical carcinogenesis in vivo2. However, our results indicate that these glucocorticoid hormones do not suppress in vitro malignant transformation that has been induced by X rays alone. These results suggest that promotion in vivo2 or in vitro9,10 that occurs in the presence of TPA is different from the natural expression of carcinogenesis in vivo or transformation in vitro effected by exposure to a high dose of a carcinogen such as X-ray irradiation. A similar conclusion was reached in other experiments involving the suppressive effects of several protease inhibitors on X-ray transformation with or without enhancement by TPA<sup>11,12</sup>. Scribner and Süss<sup>13</sup> have recently reviewed other evidence for the non-equivalence of complete carcinogenesis, brought about by exposure to a high dose of a carcinogen, and the initiation-promotion carcinogenesis regimen, brought about by a low dose of carcinogen followed by TPA promotion. Cortisone, in that it induced transformation by itself and significantly increased the yield of transformants expected for radiation treatment alone, was similar to  $17\beta$ -oestradiol in its actions on C3H  $10T_2^1$  cells<sup>14</sup>.

Previous quantitative observations on radiation transformation of  $10T_2^1$  cells agree with published data on radiation carcinogenesis in experimental animals, in terms of doseresponse relationships and the effects of factors such as dose rate, linear energy transfer and modifying agents (for review, see ref. 9). These results suggest that the response of  $10T_{\frac{1}{2}}^{\frac{1}{2}}$  cells may be related to the induction of cancer in animals, which is thought to be closely related to carcinogenesis in humans (for review see ref. 15). Thus we believe that our results may have implications for patients treated with a combination of glucocorticoids and cytotoxic agents. For example, patients undergoing total nodal

radiation and combination chemotherapy (which includes glucocorticoid treatment) for Hodgkin's disease have an elevated incidence of secondary leukaemia and lymphoma This has commonly been thought to be caused by exposure to combinations of X rays, alkylating agents and procarbazine; our results also implicate glucocorticoids. In addition, patients who are undergoing chronic immunosuppression by glucocorticoids (organ transplant patients) also have an elevated incidence of Thus, malignancy in transplant patients may be malignancy due not only to immunosuppression itself but also to the agents used to achieve this status. Our results lead us to speculate that when the clinical efficacy of glucocorticoids is similar, dexamethasone may give a decreased risk of tumour formation compared with cortisone.

We thank Mr Gary Murphy and Ms Marilyn Collins for technical assistance. This research was supported by NIH grants CA-22704, CA-21848 and ES-00002.

Toxicology is the study of the reactions, both adverse and compensatory, of living creatures to noxious materials. The hazards to which man is exposed and the manner in which he reacts to them from the moment of conception and thereafter throughout life is the subject of Human Toxicology. This new journal embraces both animal research, where it has a direct significance for man, and studies on man himself. These studies may be biochemical, physiological, pathological, clinical and epidemiological but will all be designed to increase our understanding of the action of noxious substances in the body and of means to counter their effects. All papers will be subject to peer review.

#### CONTENTS VOLUME ONE NUMBER ONE

#### **Editorial**

A Message from the Chairman of the Editorial Board — Professor Roy Goulding.

Human Toxicology: Major Issues Illustrated in the First Issue — Professor Paul Turner.

**Papers** 

Analgesic Poisoning: a Multi-centre, Prospective Survey — National Poisons Information Service Monitoring Group.

Information Service Monitoring Group.

Haemoperfusion in "Late" Paracetamol Poisoning — M. Helliwell, A. Vale and R. Goulding.

Agent Orange Toxicity: a Quantitative Perspective — Kingsley M. Stevens. Respiratory Tract Reactions to Western Red Cedar — A. D. Blainey, V. A. I. Graham, M. J. Phillips and R. J Davis.

Acute Studies to Investigate the Mechanism of Action of Caffeine as a Teratogen in Mice — M. M. A. Elmazar, Patricia R. McElhatton and F. M. Sullivan.

Severe Renal Failure in Hydralazine-Induced Lupus — A. J. Sinclair and S. J. Warrington.

Renal Failure Complicating Feprazone Treatment — Colin Robertson, Sheila Innes and James Paton.

## BRL® PRODUCT REVIEW

Bethesda Research Laboratories, Inc., P.O. Box 6009, Gaithersburg, MD 20877 BRL GmbH Offenbacher Strasse 113, 6078 Neu Isenburg West Germany BRL Bethesda Research Laboratories (UK) Ltd. P.O. Box 145, Science Park, Cambridge, England CB4 4BE

#### Hybridoma Screening Kit

BRL offers a complete Hybridoma Screening Kit which contains sufficient enzyme-coupled anti-mouse Ig and substrate to conduct 4,000 individual screening assays. β-galactosidase conjugated to sheep IgG-F(ab')2 anti-mouse IgG (heavy and light chain) is the second antibody in the Hybridoma Screening Kit. This antibody conjugate reacts with all murine immunoglobulin classes, but does not bind to target cells or plastic surfaces via its Fc portion, making it an ideal screening reagent for hybridoma products as well as for classical determination of mouse immunoglobulin levels. Included in the Kit is the substrate for  $\beta$ -galactosidase, p-nitrophenyl- $\beta$ -D-galactoside (PNPG).

Please Circle No. 10 on the Reader Enquiry Card

#### **Immunoprecipitin**

BRL® Immunoprecipitin is a highly specific and stable reagent prepared from formalin-fixed Staph A cells for selective adsorption of IgG molecules. BRL® Immunoprecipitin binds IgG within seconds and with high adsorption capacity ( $\geq 8 \mu g$  of purified rabbit IgG per mg of Immunoprecipitin) to provide an ideal solid phase adsorbant for precipitating antigen-antibody complexes and isolating/detecting specific antigens. The complexed antigen can be eluted almost completely for analytical and preparative purposes using a variety of solvent systems. When coupled with the BRL® Hybridoma Screening Kit, Immunoprecipitin can be used to detect monoclonal antibodies in hybridoma preparation.

Please Circle No. 56 on the Reader Enquiry Card

#### Protein A Agarose

Bethesda Research Laboratories announces the availability of Protein A Agarose, prepared by covalently coupling purified Protein A to 4% cross-linked agarose beads. Protein A binds specifically to the Fc region of the IgG without interfering with the antigen binding site. Protein A Agarose can be used to purify IgG, fractionate cells, and isolate antigen-antibody complexes. Protein A Agarose contains 1.8-2.5 mg of Protein A bound per ml of gel

Please Circle No. 57 on the Reader Enquiry Card

#### Product Review-ASCB Exhibition.

Bethesda Research Laboratories is exhibiting these and many other new products at the 21st Annual Meeting of the American Society for Cell Biology, being held November 9 through 13 at the Anaheim Convention Center in Anaheim, California. Stop by our exhibit booths #85, 86, and 86A to see our products displayed, discuss them with our staff, and take pertinent information home to your lab. If you will not be attending the meeting and want further information on any of these products, circle the appropriate numbers on the Reader Enquiry Card bound inside this journal.

## Fibronectins: Antigen and Antibody Products

Fibronectins are high molecular weight adhesive glycoproteins found in plasma and on cell surfaces. Although biochemically and immunologically similar, cellular and plasma fibronectins are not functionally identical. Fibronectins from both sources possess the ability to enhance the attachment of cells in culture to the usual substrates and to induce the spreading of cells. However, cellular fibronectin is 50 to 100 times more effective both in aggregating red cells and in restoring normal morphology to transformed cells in culture. Each product is supplied with a BRL Product Profile with specific product information and details of quality control assays.

#### Mouse Monoclonal Anti-Human Fibronectin (MCA-HFn)

Mouse Monoclonal Anti-Human Fibronectin is an IgG antibody that reacts with the plasma and cellular forms of fibronectin as determined by immunofluorescence assay. Each lot is assayed for Protein A binding, cytotoxicity, and antibody titer. Available now, MCA-HFn is the first in a series of monoclonal antibodies to extracellular matrix components.

#### Monospecific Antibodies to Human Plasma Fibronectin

The IgG fraction from antisera produced in rabbit and goat is purified by ammonium sulfate fractionation and ion exchange chromatography. These fractions are homogeneous as determined by SDS-PAGE (heavy and light chains) and the specificity is assayed by immunoelectrophoresis.

#### Monospecific Antisera to Human Plasma Fibronectin

Monospecific antisera to human plasma fibronectin is produced in rabbits and goats. The specificity of the antisera is established by immunoelectrophoresis. The specific antibody content is determined for each lot by quantitative precipitin analysis.

## Human Cellular Fibronectin (HC-Fn)

Human Cellular Fibronectin is affinity purified from human foreskin fibroblasts and is supplied frozen in 100 mM CAPS buffer, pH 11.0 at a concentration of 1 mg/ml

## Human Plasma Fibronectin (HP-Fn)

Human Plasma Fibronectin, purified to homogeneity by gelatin-agarose affinity chromatography, is supplied as a lyophilized solid. Purity is established by SDS-PAGE and each lot is assayed for cell spreading activity.

## Chick Cellular Fibronectin (CC-Fn)

Chick Cellular Fibronectin is isolated from chick embryo fibroblasts and purified to homogeneity by urea extraction procedures. CC-Fn is supplied frozen in 100 mM CAPS buffer, pH 11.0 at a concentration of 1 mg/ml

## Bovine Plasma Fibronectin (BP-Fn)

Bovine Plasma Fibronectin is a partially purified product especially suited as a supplement for routine tissue culture. Available as a lyophilized powder, each lot is assayed for cell spreading activity.

Please Circle No. 58 on the Reader Enquiry Card

## **NEW ON THE MARKET**

Portable pH meter. Gallenkamp has introduced a new portable pH meter with a LCD powered by rechargeable batteries, which has a low current drain, allowing much longer intervals between charges than its LED counterparts. The electrode has a built-in temperature compensation sensor. Housed in a plastic body to protect against mechanical shock and to enable light stirring of test liquids, the pH meter is slim enough to obtain readings in a test tube.

Circle No. 100 on Reader Enquiry Card.

Flatspin stirrers. A new approach to magnetic stirring has been used by Baird & Tatlock in their flatspin stirrer range. The conventional drive motor has been removed and motion is imparted to the magnetic follower or 'flea' by a rotating magnetic field which is generated between fixed coils. This provides a 'solid-state' stirrer which has no moving parts inside the case, just four solenoid coils and electronic circuitry. As there are no bearings or rotational components, the normal problems of lubrication and balancing have been removed. Another version, the 'Hotspin', has operating coils housed inside a die-cast aluminium hotplate, the temperature of which is controlled by a thermistor sensor. This provides a controlled temperature of up to 250°C.

Circle No. 101 on Reader Enquiry Card.

Micromeasuring optical system. A new model of the HMOS micromeasuring optical system has been introduced by Nikon Inc. The model 3 can be used with any Nikon microscope to make highly accurate, repeatable and quick measurements of microfine lines, particles and curved shapes. While the operator is looking through the microscope binocular eyepiece, he first positions a visible marker image at one end of the object to be measured and rotates the HMOS measuring drum until the target moves to

the other end of the object. The distance travelled is displayed directly on a digital readout. Improvements incorporated in the model 3 include a redesigned target shape and a new micrometer-digital encoder that makes over five times the number of counts per revolution than did its predecessor, to provide a digital readout to  $0.01~\mu m$ .

Circle No. 102 on Reader Enquiry Card.

Precision balance. A new type of precision balance from Pag Oerlikon offers a 'floating range' of 500,000 or 50,000 g. All Precisa balances are available with a multidata interface and various calibration standards.

Circle No. 103 on Reader Enquiry Card.

IR distancer. The new infra-red distancer from Wild Heerbrugg, the Distomat DI20, has a measuring range of up to 14 km, with an accuracy of  $\pm$  5 mm + 1 p.p.m. The standard measuring program takes only 6 s to display the distance. The instrument also has a tracking program which updates readings to a moving object at 1-s intervals and a repeat mode that updates the mean where maximum accuracy is required. Its test mode informs the user at the touch of a key about standard deviation, receivedsignal strength and battery state. The instrument can be attached to the Wild T1, T16 and T2 theodolites; it can also be supplied with provision for electronic recording of slope distance.

Circle No. 104 on Reader Enquiry Card.

Slab gel dryer. New from LKB Instruments is a slab gel dryer which offers accelerated drying times. The LKB 2003 slab gel dryer allows synchronous control of both heat and vacuum sources through a built-in timer and timed outlet to produce fast drying times for all electrophoresis and electrofocusing gels. A 500-W heating element uniformly heats the large  $18 \times 35$  cm drying area to  $80 \pm 2^{\circ}\text{C}$  while a thermal cut-off fuse guards against accidental overheating. The unit is resistant to the acid fumes and organic vapours normally produced during the drying process.

Circle No. 105 on Reader Enquiry Card.

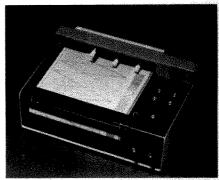

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the journal.

HPLC guard columns. The new SSI guard column, designed specifically for SSI end fittings, protects the analytical packing from degradation or dissolution by aggressive mobile phases, and from contamination by sample impurities such as particles or precipitated traces of protein. The refillable guard column may be tap-packed with a pellicular packing or slurry-packed with 3, 5 or 10 µm material to match the analytical column. The tip of the guard column is made of material acceptable to HPLC and is designed to seal in the ferrule seat of the end fitting to 5,000 p.s.i. By eliminating any extra tubing or connectors, void volume is kept to an absolute minimum.

Circle No. 106 on Reader Enquiry Card.

Collection of blood samples. A blood gas Monovette for collection of blood samples for arterial blood gas determinations, is available from Sarstedt, Inc. The unbreakable polypropylene Monovette incorporates a plunger configuration which assures that samples are taken and kept in anaerobic conditions. Preparation with lithium heparin ensures correct anticoagulant concentrations.

Circle No. 107 on Reader Enquiry Card.

Integrating recorder. The new Linear 200 series integrating recorders are available in single and dual channel models, each with one integrating channel. These recorders incorporate an electro-mechanical integrator. Peak heights are displayed on one channel during integration and recording of the area under that particular curve. Integrator count rates are 3,000, 6,000 and 12,000 counts per min or per h. The chart width is 250 mm; overall limit of error <±1%, chart speeds: 1, 2, 4, 10, 20 and 40 cm min<sup>-1</sup> or cm h<sup>-1</sup>; full-scalesspans of I and 10 mV.

Circle No. 108 on Reader Enquiry Card.

Ion-exchange TLC. Fixion plates for ion-exchange TLC consist of a strong cation exchange resin, the  $50 \times 8$ , and the  $2 \times 8$ , a strong anion exchange resin. These plates have been used to separate amino acids, nucleic acid components, peptides and pharmaceuticals. A leaflet describing them can be obtained from HPLC Technology. Circle No. 109 on Reader Enquiry Card.

Urine container. Designed for the collection of urine samples over a 24-h period, the Tulip 2500 from L.I.P. has a large built-in funnel and moulded handles that remove discomfort in use and ensure clean collection of the sample on each occasion. The container, when expanded, contains 2.5 litres but is supplied in collapsed form to save storage space. Patient details can be included on the moulded label around the top of the graduated container.

Circle No. 110 on Reader Enquiry Card.

Electrofocusing. The measurement of pHprofiles in polyacrylamide, the most widely used medium, could previously only be performed by slicing out the appropriate pieces of gel, eluting the ampholyte and measuring the pH of the solution, or by using a soft-surface microelectrode and a pH meter. A new electrophoretic development from BDH Chemicals removes all the difficulties and limitations of these methods: the use of a series of highly purified lyophilized coloured protein standards on electrofocusing media provides a continuous focusing guide, allowing accurate assessment of when the focusing is complete. The gel and standards can be dried to provide a permanent experimental record for comparative purposes. This product is described in a booklet 'Isoelectric Point Markers'

Circle No. 111 on Reader Enquiry Card.

## Biosearch Makes Oligonucleotides

- Custom synthesis of oligonucleotides Two to three week delivery time Sequence verified by Maxam Gilbert
- Blocked nucleosides for phosphitemediated syntheses
- Blocked dimers and trimers for phosphotriester syntheses
- Full line of linkers, adapters, primers and probes
- Full spectrum of reagents for solid phase oligonucleotide synthesis
- Custom preparation of DNA-protein conjugates for raising antibodies to specific DNA sequences

Please inquire about our comprehensive line of immunochemicals, neuroagonists/ antagonists, enkephalins and other bioactive peptides.

Circle No.36 on Reader Enquiry Card.

Variable-wavelength UV monitor. Designed for HPLC applications which require high sensitivity with low noise and drift, the new Bio-Rad 1305 variable wavelength UV monitor provides digital readout of absorbance, transmittance or photodetector output, independent of the recorder. The standard deuterium lamp gives a  $190 - 350 \mu m$  wavelength range, and an optional tungsten lamp extends the range from 350 to 600  $\mu m$ . The monitor features separate electronic and optical modules to conserve bench space, and interchangeable cassette-type flow cells for analytical, preparative and classic opencolumn chromatography.

Circle No. 112 on Reader Enquiry Card.

Bench centrifuge. The new bench centrifuges from Baird and Tatlock feature lid interlock, out-of-balance cut-out and indicator, reinforced chamber, sealed buckets and sealed chamber with outlet vent for ducting. The MkIV auto bench centrifuge has electronically optimized automatic braking and acceleration.

Circle No. 113 on Reader Enquiry Card.

Pocket radiation monitor. Philips have designed a new lightweight pocket radiation monitor for measuring exposure rate and accumulated dose. This compact unit (PW 4514) measures  $\beta$ , X-ray and  $\gamma$ radiation. A four-digit LCD shows both monitoring functions, and a clearly audible alarm sounds if the exposure rate exceeds any of six pre-set levels - 0.5, 2.5, 10, 25, 100 and 250 mR h-1. The alarm continues for a minimum of 5 s so that even momentary excesses are drawn to the user's attention. Maximum exposure rate measurable is 999 mR h-1. The PW 4514 has applications in hospital radiology and isotope laboratories, nuclear power stations and analytical X-ray labs.

Circle No. 114 on Reader Enquiry Card.

Ionization gauge head. Instrument Technology have produced a triode ionization gauge head, suitable for use where pressure readings < 10<sup>-7</sup> torr are not required. In this VIG.71 series, the gauge has an Octal base and can be supplied with push-on connector and safety lead. This gauge head supplements Instrument Technology's VIG.30 series of UHV gauges and, like these, can be connected to a vacuum system, either by direct fusion to glass, or by means of the captured copper gasket and stainless steel flange.

Circle No. 115 on Reader Enquiry Card.

Recording magnetometer. High-sensitivity measurement of the Earth's magnetic field is possible using the G-866 recording magnetometer from EG&G Geometrics. Designed for airborne, marine, land mobile or base-station operations, the microprocessor-controlled G-866 provides resolution to 0.1 gamma and features a built-in digital printer and strip-chart recorder, real-time clock, push-button tuning and sample interval selection ranging from 2 readings per s to 1 reading every 999 s. The chart recorder uses an electrostatic digital plotter mechanism to permanently record data as a dualsensitivity analog chart, annotating the record with exact readings, time, date and scale factors.

Circle No. 116 on Reader Enquiry Card.

Salinometer. A new induction salinometer designed for all marine science applications has been announced by Beckman. The model RS9 is lightweight and provides rapid, accurate measurements of seawater salinity. Salinity determination in the range  $0-51^{\circ}/_{0.0}$  at an accuracy of  $\pm 0.0003^{\circ}/_{0}$ can be made in less than 1 min. The model RS9 can be interfaced with an optional Hewlett Packard model HP-97S calculator, thus eliminating the need to look up salinity in the International Oceanographic Tables. A permanent record of the sample number, salinity, conductivity ratio, temperature and chlorinity is also provided.

Circle No. 117 on Reader Enquiry Card.

Programmable sample changer. Varian has released a new microcomputer-programmed sample changer, designed primarily for use with atomic absorption spectrophotometers. The PSC-55 may be keyboard programmed to take multiple readings for each sample, rinse at a selected frequency, and perform a re-calibration of slope after a specified number of samples. The sample changer can handle 67 samples, 5 standards, a blank, a re-slope standard and a large reservoir of rinse solution. Samples may be placed in either standard test tubes or disposable microvials. The PSC-55 has a microsampling mode, used when the sample volume is limited or the solution contains large amounts of dissolved solids, by which reliable measurements can be obtained for  $< 100 \,\mu l$ 

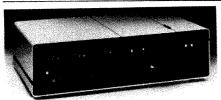

Circle No. 118 on Reader Enquiry Card.

Cryogenic preparation. Hydrated biological specimens for direct scanning electron microscope observation can be prepared using the new SP2000 sputter cryo system from Emscope Laboratories. This system will interface readily to any scanning electron microscope and includes facilities for freezing, fracturing, sputtercoating, sublimation and etching, which allows it to be used in all areas of routine and research biological scanning EM.

Circle No. 119 on Reader Enquiry Card.

Hot agar dispenser. Using the bubble eliminator from Kraft Apparatus, bubble-free agar can be dispensed accurately. The pumping head features total ball-bearing construction and variable volumes per unit time can be dispensed using the variable speed motor. Delivered volume is adjustable from 2 to 575 ml with 1.5 reproducibility.

Circle No. 120 on Reader Enquiry Card.

lonized calcium analyser. A computerized system that measures ionized calcium and pH for 125-µl samples of whole blood, plasma or serum has been introduced by Radiometer. In addition to these direct measurements, the ICA1 calculates ionized calcium at pH 7.4. The measurements are based on ion-selective electrodes. A calcium-ion-sensitive electrode a pH electrode and a common reference electrode are all mounted in a measuring chamber, maintained at 37°C. The ICA1 has a built-in monitoring system: all parts and functions are checked by the computer.

## AUTHORS WANTED BY N.Y. PUBLISHER

A well-known New York subsidy book publisher is searching for manuscripts worthy of publication. Fiction, nonfiction, poetry, juveniles, travel, scientific, specialized and even controversial subjects will be considered. If you have a book-length manuscript ready for publication (or are still working on it), and would like more information and a free booklet, please write:

Vantage Press, Dept. D-69
516 W. 34th St., New York, N.Y. 10001

Circle No.51 on Reader Enquiry Card.

Tracking animal movements. The Videomex system from Columbus Instruments consists of a vidicon TV camera and Apple-II personal computer, and allows automatic tracking of animal movements within the observation field of the camera. The x-y coordinates of the animal are computed and plotted on a computer printout. Programs available allow computation of the distance the animal travels, number of small and large movements, and time spent moving and resting. Animal rotational behaviour is detected automatically - this is an important test of pharmacological compounds with dopaminergic activity. The number of clockwise and counterclockwise turns, as well as incomplete turns, of the animal are counted.

Circle No. 122 on Reader Enquiry Card.

Ion implantation system. Varian has developed a new multi-purpose ion-implanter system — the DF-3000 — evolved from the 200-DF5, the industry standard for medium-current ion implanters. The new system, with up to 300% increase in scanned beam current, reduces the time required to achieve highly uniform implants. In addition, the DF-3000 reduces problems of wafer contamination due to particulates common in earlier ion-implantation equipment. The system offers scanned beam currents of 1,500 μA for P and 1,250 μA for As.

Circle No. 123 on Reader Enquiry Card.

#### **NEW LITERATURE**

Test and measuring instruments. A range of oscilloscopes, chart recorders, frequency counters and logic analysers is described in a new catalogue from Enertec Instrumentation Ltd. Circle 150.

**Chromatography.** Additions to the Dionex range of chromatography products are listed in a new catalogue. Circle 149.

Reactors and pressure vessels. The complete Parr line of laboratory reactors and pressure vessels is described in a new catalogue. Information on operating pressures, temperatures, construction materials and accessories is included. Circle148.

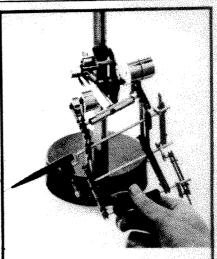

**pH** monitoring. New literature from Beckman Instruments describes their **pH** monitoring system, designed for waste water applications. Circle 147.

**Electrophoresis chamber.** The new 600 electrophoresis chamber is described in a brochure from Shandon. Circle 146.

**Radioactive solutions.** Amersham have produced a standardized radioactive solutions catalogue. Circle 145.

Hybridization technology. Schleicher & Schuell, Inc. have brought out 'Products for Nucleic Acid and Protein Research', which surveys solid-support hybridization techniques. Circle 144.

Copies of these publications can be obtained using the reader enquiry card.

## SINGER MICROMANIPULATORS ARE FAMOUS BECAUSE

Singer Micromanipulators enable anyone to make exact movements without tremor or lost motion, in three dimensions, using a single control handle under low or high power magnification.

A varied range available. All simple to operate.

SINGER INSTRUMENT CO. LTD., Treborough Lodge. Roadwater, Somerset.

Circle No.34 on Reader Enquiry Card.

Our thermoelectric Tissue Freezer BFS-2 makes them easy to cut. Temperature is adjustable for optimum sectioning. No more dry ice or CO<sub>2</sub> gas, fits all microtomes, always ready. Hundreds in use.

CANCELLATIONS MUST BE RECEIVED NO LATER THAN 5 p.m. ON THURSDAYS PRIOR TO ISSUE DATE.

#### CHRISTIE HOSPITAL AND **HOLT RADIUM INSTITUTE**

PATERSON LABORATORIES

#### **MEDICAL LABORATORY** SCIENTIFIC OFFICER

required for work in a Histopathology Laboratory providing a service to biological research units.

Qualifications: ONC or HNC in Medical Laboratory Sciences (Histopathology) or equivalent experience.

Salary: £2,725 to £4,350 or £4,958 to £6,993 pa according to age, qualifications and experience. Day release available where required.

Applications to Laboratory Administrator, Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester M20 9BX, quoting reference PL/81/6 and enclosing SAE. Closing date: 16th November 1981. (9843)A

#### POST DOCTORAL RESEARCH ASSOCIATE

Position is available immediately to study the molecular basis of surface glycoprotein gene expression in African trypanosomes and to initiate studies on surface antigen gene expression in leishmania parasites. Only candidates with research experience in biochemistry or preferably molecular biology will be considered. Position for up to two and a half years with a negotiable salary range of \$13,000 to \$15,000.

Please send all inquiries and/or curriculum vitae and names of two references to: Dr Kenneth B Marcu Biochemistry Department, SUNY Stony Brook, Stony Brook, NY 11794. SUNY Stony Brook is an equal opportunity/affirmative action employer. AK 205

(NW043)A

#### INSTITUTE OF CHILD HEALTH University of London

#### PRE OR POST DOCTORAL RESEARCH SCIENTIST

required as soon as possible for three year project to investigate the immunological factors controlling tolerance to food antigens and their disturbance in diseases caused by food allergy. Initial salary within the range £5,285 — £6,475 plus £967 London Weighting per annum (University scales 1A or 1B for Research and Analogous Staff). Opportunity to register for a higher degree, if required.

Further information from Dr R J Levinsky or Dr M W Turner, Immunology Department, Institute of Child Health, 30 Guilford Street, London WC1N 1EH. Tel: 01-242 9789 ext 133 or 130. (9840)A

#### FRIEDRICH-MIESCHER-LABORATORIUM OF THE MAX-PLANCK-GESELLSCHAFT TUEBINGEN, GERMANY

research associate position is available for at least two years in a new independent group working on aspects of the cytoskeleton, the cell surface, and cell secretion (see PNAS 77, 4108 (1979); Cell 22, 555 (1980), TIBS 6, 234 (1981)).

As techniques, monoclonal antibodies and microinjection with glass capillaries are used. The salary will be according to a German BAT Ila/Ib position and be about DM 30,000 to 40,00 per year.

Applications with references (incl. number) should be sent to Dr Walter Birchmeier, Laboratorium für Biochemie, Federal Technical University (ETH), CH-8092 Zürich, Switzerland. (W484)A

# Sr. Research Biochemical Engineers

You've probably heard that Merck Sharp & Dohme Research Laboratories has one the largest R&D budgets in the pharmaceutical industry. For innovative engineers and scientists, that translates into exceptional opportunities to achieve new breakthroughs. Both in pharmaceutical and biological products. And in your career.

We're now seeking two scientists/engineers with PhD degrees and postdoctoral/industrial experience in these areas:

- INDUSTRIAL MICROBIOLOGY
- **FERMENTATION TECHNOLOGY**
- EUKARYOTIC GENETIC ENGINEERING

- IMMUNOCHEMISTRY
- **BIOENGINEERING**

Positions will involve process research, development and scale-up of microbial fermentations, cell culture systems and macromolecular product isolations. Specific requirements include PhD degree (or equivalent) in Chemical Engineering/Biochemistry/Microbiology, with at least one degree in Chemical/Biochemical Engineering. Demonstrated leadership capability is essential. Postdoctoral work preferred; as is strong background in biochemistry, virology, microbiology, separation engineering or recombinant DNA microorganisms.

Growth opportunities are complemented by excellent salaries and outstanding benefits. Send résumé with salary requirements to Ms. Johanna Y. Zeltner, Ref. NA-1.

P.O. Box 2000, Rahway, New Jersey 07065

An equal opportunity employer m/f

(NW035)A

# Radio Astronomy Research & Development Overseas

Goal-orientated R&D work on a 3-year contract or permanent basis with a world leader in South Africa.

The National Institute for Telecommunications Research carries out research into all aspects of radio and its applications. We have been responsible for a number of significant technological breakthroughs including 2 world 'firsts': inventing the Tellurometer and subsequently developing an infra-red distance measuring system. Achievements that we attribute largely to our policy of actively encouraging initiative at all levels.

The Radio Astronomy Observatory is situated in a pleasant, protected valley about 35 miles from Johannesburg. The telescope has a 26 metre diameter and operates under

computer control.

With minimum supervision and maximum observation time, you will be able to study radio emissions from astronomical objects, analyse/interpret results, give occasional lectures and possibly assist with the instrumentation and computer software development. Both team and individual

project work are involved.

Consequently you should possess at least a BSc (Hons) with a physics, astronomy, computing or electronics background. These posts will prove very attractive to those of you currently holding posts with established radio astronomy observatories.

The CSIR was established to develop the Republic's research-oriented manpower, material resources and national/community services through 4,500 personnel employed at 19 research laboratories and institutes nationwide.

**COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH** 

Whether you choose to join us on a 3-year contract (renewable) or permanent basis, salaries are negotiable and these will be augmented by the Republic's high standard of living at relatively low cost (at least 30% below that of the UK) plus the following benefits • free air passages (both ways for contract appointees) • assistance with removal costs

- settling-in allowance generous house purchase scheme, where applicable annual bonus equal to one month's salary medical aid, pension/life assurance schemes
- outstanding schooling (English-medium), sports and recreational facilities, etc.

In addition, researchers' findings may be used as a basis for Master's and Doctoral dissertations.

For an application form, either ring 01-242 1766 during normal office hours or send brief personal and career details

in the UK.

(including phone number) to the Scientific Counsellor, Chichester House, 278 High Holborn, London WC1V 7HE, quoting reference 11/1/686 clearly on your envelope. All interviews will be conducted

(9838)A

#### CAWTHRON INSTITUTE NELSON, NEW ZEALAND

invites applications for the position of

## **Research Microbiologist**

to work on microbial fermentation and the processes involved in transforming biological products and wastes into other compounds.

A qualified research scientist with training and experience in biotechnology and microbial physiology and biochemistry will be given wide scope to investigate innovative ways of converting materials and evolving new processes which might lead to the development of interesting and useful compounds e.g. fuels, pharmaceuticals, enriched feeds, foods, biochemicals etc.

The position requires a good researcher with the drive, initiative, and versatility to develop a programme of investigation.

The appointee will join a small research group of microbiologists engaged in laboratory and field investigations of a number of microbial processes e.g. methanogenesis, nitrification, denitrification, phosphate mobilisation, and fermentation.

The appointment will be for an initial period of three years with the possibility of reappointment.

Salary will depend on age and experience and will be within the range NZ \$15,23,000.

Fares to Nelson and reasonable expenses for transport and personal goods and effects will be paid to appointee and dependent family.

Applications (3 copies) containing full curriculum vitae, a recent photograph and the names of three referees should reach the Director, Cawthron Institute, Box 175, Nelson, New Zealand not later than 20 November 1981. (W483)A

# UNIVERSITY OF NEWCASTLE UPON TYNE THE DENTAL SCHOOL LECTURER IN ORAL PHYSIOLOGY

Applications are invited for the post of LECTURER IN ORAL PHYSIOLOGY

in the new Department of Oral Biology. The post is open to candidates with or without dental qualifications who are interested in physiological or biochemical research, for which there are excellent facilities in the Department. The successful candidate will be required to undertake undergraduate and postgraduate teaching in oral physiology and to participate in research

Salary will be at an appropriate point, according to age, qualifications and experience, on the Lecturers' Pre-Clinical scale £8,105 — £12,860 per annum for dentally qualified candidates or on the Lecturers' scale £6,070 — £12,860 per annum without dental qualifications.

Further particulars may be obtained from the Deputy Registrar (FP), The University, 6 Kensington Terrace, Newcastle upon Tyne NEI 7RU, with whom applications (3 copies), together with the names and addresses of three referees, should be lodged not later than 21st November 1981. Please quote reference N.

(9821)A

INSTITUTE of Cancer Research: A Post-Doctoral Fellow is required for the Division of Cell and Molecular Biology, Chester Beatty Research Institute, Fulham Road, SW3, to work on the isolation and characterisation of eukaryotic chromosomal proteins. Experience in amino acid sequencing would be an advantage but general experience in protein chemistry would be acceptable. The post is for two years in the first instance with a possible extension of one year. Starting salary in range £6,070 — £7,700 pa plus London Allowance of £967 pa. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting Ref. 300/G/12. (9827)A

#### CHURCHILL HOSPITAL Medical Genetics Dept, Old Rd, Headington SENIOR SCIENTIFIC OFFICER

A vacancy occurs in the Department of Medical Genetics from March 1982 for a Senior Scientific Officer. The successful applicant will have an appropriate degree, plus several years experience in human cytogenetics. The salary range is from £8,134 to £10.516.

In the first instance send for an application form to Dr R H Lindenbaum, Department of Medical Genetics, Old Rd, Headington, Oxford OX37LE. (9830)A

# IMMUNOLOGY PHARMACOLOGY MOLECULAR BIOLOGY RESEARCH

SmithKline, a leader in pharmaceutical research, is undertaking a major expansion of its research division. Applications are invited from research scientists (Ph.D./ M.D./ D.V.M./ M.S./ B.S.) to join interdisciplinary research teams to participate in the development of new therapeutic agents in a stimulating environment that offers significant opportunities for innovative research.

Our scientists are encouraged to publish, to hold adjunct academic posts and to interact fully with the national and international scientific community. A new, superbly equipped \$27 million research facility is under construction at our Upper Merion research campus in suburban Philadelphia and will be completed in 1982. This represents the first stage of a \$200 million R&D facility under construction at this site for completion by 1985.

We are seeking outstanding individuals at all seniority levels who have expertise in one or more of the following subjects:

# **IMMUNOREGULATION**

(ref: MB-1)

identification of lymphoid cell subsets / cell sorting /lymphokines/macrophage physiology/auto-immune diseases

# HYBRIDOMA TECHNOLOGY (ref: MB-2)

hybridoma production / characterization of monoclonal antibodies/ cell sorting

# MOLECULAR GENETICS (ref: MB-3)

DNA sequencing/nucleic acid enzymology/gene construction/gene cloning and expression in Bacillus, actinomycetes, yeast and mammalian systems/promotor regulation/gene amplification

# FERMENTATION TECHNOLOGY

(ref: MB-4)

whole cell and enzyme immobilization / fermentation methods/biochemical and fermentation process engineering

# **CELL BIOLOGY**

(ref: MB-5)

large scale mammalian cell culture 7 cell fusion / microinjection/bone marrow and tumor stem cell cloning/platelet physiology/mutagenesis/electronmicroscopy/subcellular fractionation

# ENZYMOLOGY AND PROTEIN CHEMISTRY

(ref: MB-6)

protein sequencing/peptide synthesis/ isolation and purification of lymphokines and cytokines / macromolecular separation / radioimmunoassays/microanalysis/instrumentation development

# RECEPTOR BIOLOGY

(ref: MB-7)

# ADMIRALTY UNDERWATER WEAPONS ESTABLISHMENT Portland, Dorset

A vacancy exists for a

# Junior or Senior Research Fellow

to study the application of MACHINE INTELLIGENCE techniques, including EXPERT SYSTEMS and FUZZY REASONING, to naval problems. The successful applicant will work at Portland, but will be expected to co-operate closely with researchers at the University of Bristol and elsewhere. Candidates will be expected to demonstrate an excellent record of research. It might be possible for a suitable applicant without a PhD to use this work as the basis for a submission. The appointment will be for a fixed period of up to three years.

Depending on qualifications and experience, the stipend will be in one of the following ranges:

JUNIOR RESEARCH FELLOW £6,302 — £7,507 (Minimum of two years post-graduate research experience, not necessarily in a directly related subject).

SENIOR RESEARCH FELLOW £8,596 to £9,676 (Minimum of three years postgraduate research experience in a directly related subject).

All candidates must have a first or second class honours degree.

Application forms may be obtained from the Scientific Personnel Officer, Admiralty Underwater Weapons Establishment, Portland, Dorset DT5 2JS. Telephone: Portland (0305) 820381 ext 3433.

Please quote reference: AX787/U/151.708/AXS. Closing date for applications 27th November 1981. (9822)A

# Biological Scientist

# **Fruit Preservation**

Tate & Lyle are developing coatings for fruit as preservation and storage aids. This work has created a need for an honours graduate with 3-5 years postgraduate experience preferably in post harvest physiology which could include Ph.D. and/or industrial work. The successful candidate will be qualified in a biological science and he/she will join a multi-disciplinary team engaged in studying means of controlling the ripening of fruit. The group conducts fruit trials and looks at biochemical and biophysical effects related to the ripening process. Salary and benefits are competitive. Please apply with CV to:

Salary and benefits are apply with CV to: Personnel Manager, Tate & Lyle Group Research & Development, P.O. Box 68, Reading RG6 2BX.

# UNIVERSITY OF GUELPH WILDLIFE BIOLOGIST

The Department of Zoology offers a faculty position at the assistant or associate professor rank for a wildlife biologist. The successful applicant will be expected to teach undergraduate courses including wildlife management and biology.

Candidates must have at least 2 years post-doctoral experience and will be expected to develop a research and graduate program.

Position to be filled by April 1st, 1982 subject to final budgetary approval.

Application, including a curriculum vitae with the names of three referees should be sent to: The Chairman, Department of Zoology, College of Biological Science, University of Guelph, Guelph, Ontario N1G 2W1.

Only those applicants legally eligible to work in Canada need apply. (NW034)A

# UNIVERSITY OF TORONTO DEPARTMENT OF MEDICAL GENETICS ASSISTANT OR ASSOCIATE

### PROFESSORS POSTDOCTORAL FELLOWS

The University of Toronto, Department of Medical Genetics, invites applications for two positions open at either the Assistant or Associate Professor level. One position requires a background in animal models of metastasis and quantitative assay of metastatic potential. The other position requires a background in the isolation and structural identification of cell surface glycopeptides and oligosaccharides. The appointees will be expected to conduct independent research programmes in their area of expertise, as applied to the investigation of the molecular basis of metastasis. This research will be conducted within a multidisciplinary group funded for five years by a Terry Fox Special Initiatives Grant from the National Cancer Institute of Canada. Start-up funds will be provided for personnel, equipment and supplies. Opportunities for eventual permanent staff positions are excellent. Candidates must have a PhD or equivalent, and appropriate post-doctoral training. Salary and rank will be commensurate qualifications and experience. with

Three positions within the above research group are open for post-doctoral fellows with backgrounds in either of the two previously mentioned areas, or in somatic cell genetics. Salary support for three years is available for each of these positions.

Closing date for all applications is December 31, 1981. Positions will take effect April 1, 1982 or as soon as possible thereafter. Applicants are asked to submit a curriculum vitae with a list of publications, and the names of three referees to either: Dr Harry Schachter, Department of Biochemistry, Research Institute, Hospital for Sick Children, Toronto, Ontario, M5G 1X8; OR Dr Jeremy Carver, Department of Medical Genetics, Medical Sciences Building, University of Toronto, Toronto, Ontario, M5S 1A8. (NW031)A

# RESEARCH TECHNICIAN

Applications are invited from individuals to develop *in vitro* culture techniques for entomophilic nematodes and novel, biochemical methods for nematode identification. Qualifications: experience in the culture and taxonomy of entomophilic nematodes; familiarity with modern taxonomic techniques and electron microscopy; postdoctoral experience. Starting salary \$16,000 per year.

Applicants should send an outline of their research interests, a curriculum vitae and the names and addresses of two referees, as soon as possible to: Dr John M Webster, Department of Biological Sciences, Simon Fraser University, Burnaby/Vancouver, BC Canada V5A 1S6.

(NW021)A

### INTERNATIONAL LABORATORY FOR RESEARCH ON ANIMAL DISEASES Nairobi Kenya

Applications are invited from suitably qualified candidates for

### POSTDOCTORAL FELLOW Ref. No. PDF/L3/81/1

A position is available from January 1, 1982 for two years to improve laboratory technology in the study of trypanocidal drugs in vitro. Applicants must have PhD (or equivalent) in Science or Pharmacology, practical experience in cultivating African trypanosomes and various mammalian cells in vitro and solid knowledge of organic chemistry and be capable to apply above background to the project without further training on the cultivation of trypanosomes. The successful candidate will work on the joint programme with the collaboration of Cell Biology Laboratory (ILRAD), Kenya Trypanosomiasis Research Centre and GTZ-supported Chemotherapy of Trypanosomiasis Research Project/Ministry of Agriculture. This is an international post and the salary will be paid in US\$.

Applications identified with Ref: No. including CV, summary of PhD thesis, and three references should be sent by 19 November 1981 to:

CHIEF PERSONNEL OFFICER,

I.L.R.A.D., P.O. Box 30709, NAIROBI, Kenya.

(W465)A

# AGRICULTURAL RESEARCH COUNCIL VETERINARIAN

Required to join a group studying possible hazards associated with new developments of husbandry procedures. The post will provide veterinary expertise to existing research projects which include the study of the use of anabolic agents in farm animals. In particular, the applicant will investigate the endocrinological mechanisms which may control mammary development in the dairy heifer, and the relationship between fatty liver and infertility in the cow.

Salary: Veterinary Research Officer scale £10,398 × 5 to \$13,448 p.a. (depending on age and experience). Non-contributory pension

Qualifications: Applicants must be members of the Royal College of Veterinary Surgeons, with at least two years post-graduate experience, preferably in endocrinology.

The Institute is located in pleasant rural surroundings in an estate of 2,000 acres and has a staff of 295.

Application forms from: The Secretary, Institute for Research on Animal Diseases, Compton, Nr Newbury, Berks RG16 0NN, quoting reference 470. Closing date: 21/11/81.

# THE ST GEORGE HOSPITAL DIRECTOR OF PATHOLOGY

Senior Staff Specialist in Immunopathology with conjoint appointment as

# CLINICAL PROFESSOR OR CLINICAL ASSOCIATE **PROFESSOR**

School of Pathology University of NSW

Applications are invited from medical graduates with senior qualifications in pathology for the above position. The successful applicant will be responsible for participating in and supervising immunopathological services as well as directing the overall diagnostic laboratory procedures for a 600 bed Teaching Hospital of the University of NSW. The Department of Pathology is currently staffed by six full-time Specialists. It is intended that the appointee would be offered the title of Clinical Professor (Conjoint) or Clinical Associate Professor (Conjoint) and as such would be responsible to the University of New South Wales for teaching in the School of Pathology, with access to the facilities of that School.

Salary is at Senior Staff Specialist rate, \$45,695 per annum and an appropriate administrative allowance is payable. Conditions in accordance with the Medical Officers' Hospital Specialist (State) Award, include three months paid study leave each five years of service. Limited right of private practice in accordance with procedures laid down by the Health Commission is also available.

Written applications, including the names and addresses of three referees, close with the Chief Executive Officer The St George Hospital, Kogarah, NSW 2217, on 31st December, 1981. Enquiries concerning hospital duties should be directed to the Director of Medical Services phone (02) 588 1111, and on University matters to Professor A Lykke (02) 662 2771. (W477)A

### THE CASWELL SILVER DISTINGUISHED PROFESSORSHIP IN GEOLOGY THE UNIVERSITY OF **NEW MEXICO**

The Department of Geology of the University of New Mexico is pleased to invite nominations or applications for the Caswell Silver Distinguished Professorship in Geology. This endowed professorship shall be awarded for periods of up to two years to earth scientists of distinguised accomplishment and international reputation. The international reputation. The professorship may be held by scientists of all specialties of the earth sciences in the broadest sense, and the major criterion for selection is that the individual be an active, productive leader in his or her field of research. The recipient must carry out a vigorous reserch program while in residence at UNM. The recipient is expected to interact with the faculty and students of the Department and to provide one or more seminars, in an advanced topic of his/her choice, during each academic year. The Foundation will provide unusually advantageous remuneration commensurate with the distinguished nature of the appointment. In addition, a generous allocation for travel and operating expenses (to include secretarial support, analytical services in department laboratories, use of field vehicles, and preparation of manuscripts) will be provided.

Applications or nominations should includes a detailed résumé and brief statement of major research accomplishments. Applications or nominations should be forwarded to: Rodney C. Ewing,

Chairman, Department of Geology, University of New Mexico, Albuquerque,

New Mexico 87131. The deadline for applications is January 1, 1982. The Caswell Silver Foundation is an equal opportunity employer. (NW032)A employer.

# Synchrotron Radiation Research SURFACE SCIENTIST The Synchrotron Radiation Source at the Daresbury

Laboratory is the world's first high energy (2 GeV) storage ring specifically designed to provide a large number of synchrotron radiation beams. A Surface Scientist is required to assist Laboratory staff

and University users in designing, setting up and maintaining beam lines and experimental apparatus and running experiments in the general area of surface science. The apparatus involved will include two electron spectrometers for angularly-resolved photo-emission and one for x-ray absorption studies on surfaces, together with their associated optical monochromators and minicomputerbased data acquisition systems. There will be opportunities to collaborate in research projects with Laboratory and University staff.

Candidates should have a good honours degree in an appropriate discipline, post-graduate experience in surface science and specific practical expertise in some or all of the fields of ultra-high-vacuum, electronics, vacuum ultraviolet/ x-ray optics and microcomputer programming.

An appointment will be made at Scientific Officer/ Higher Scientific Officer level on the salary scale £5,176 to £6,964/£6,530 to £8,589 per annum, subject to qualifications and experience. The appointment will be superannuable. There is a generous leave allowance and a flexible

working hours scheme. CLOSING DATE: 20th November, 1981. For further information please write or telephone Warrington (0925) 65000, Ext. 239 Dr. I. H. Munro or Dr. D. Norman (Ext. 236). Application forms may be obtained from and should be returned, quoting reference number DL/773 to: The Personnel Officer, Daresbury Laboratory, Science & Engineering Research Council, Daresbury. Warrington, WA4 4ĂD. (9849)A

# THE WEIZMANN INSTITUTE OF SCIENCE is pleased to announce the availability of the Charles H. Revson Career Development Chairs

the Revson Chairs are intended for promising scientists who are eligible for appointment as senior scientists at the Weizmann Institute.

The Revson Chairs are intended for either scientists who reside in Israel or for those who are considering making their residence in that country.

The appointment for Revson Career Development Chairs are for three years. Appointees found suitable at the end of this period will be invited to continue their employment as permanent members of the Weizmann Institute's scientific staff.

Application forms and further information are available from: The Charles H. Revson Foundation Program, c/o The Academic Secretary, Weizmann Institute of Science, Rehovot 76100, (WARE)A Israel.

# **BIOLOGIST**

Expansion of the research programme has created an opportunity in our Agricultural Biology Department for a Research Assistant to join a team investigating the mechanisms of animal growth.

The job involves setting up laboratory studies using farm animals and monitoring their progress using radio-ligand assay techniques, interpretation of results and development of new assay methods.

Applications are invited from suitably qualified graudates/HNC's and those with directly relevant experience.

Our laboratories are located at Sandwich on the Kent Coast, where some 500 scientists and supporting staff are engaged in the discovery and development of novel compounds for use in human and veterinary medicine.

The starting salary will be competitive and will reflect qualifications and experience. There is good bonus potential.

Pension, death benefit schemes are in operation and there is assistance with relocation expenses. Flexible hours are worked and the social/recreational facilities are first-class.

Please write, in confidence, giving details of qualifications, experience, etc, to: G. Marshall, Personnel Officer, Pfizer Central Research, Sandwich, Kent. (9852)A

# FACULTY POSITIONS IN MOLECULAR GENETICS

The Department of Microbiology at the University of Cincinnati College of Medicine is undergoing a major expansion and invites applications for tenuretrack positions at either the junior or senior faculty level. Candidates should be involved in a vigorous and creative research program and should have demonstrated independence as laboratory investigators. Also the applicant should be an effective teacher and be able to direct graduate students. Research interests can be either in prokaryotic or eukaryotic molecular genetics. Applicants should submit curriculum vitae, a short statement of research interests and accomplishments, and the names of three scientists willing to write letters of recommendation. These should be forwarded to: Dr Jerry B Lingrel, Chairman, Department of Microbiology, University of Cincinnati College of Medicine, 231 Bethesda Avenue, Cincinnati, Ohio 45267. The University is an Equal Opportunity/ Affirmative Action Employer.

# LONDON SCHOOL OF HYGIENE & TROPICAL MEDICINE

(University of London)
Keppel Street/Gower Street,
London WC1E 7HT
DEPARTMENT OF MEDICAL
MICROBILOGY

(Head of Department: Professor A J Zuckerman) 2 MEDICAL LABORATORY SCIENTIFIC OFFICERS

1) for work in the Virology Unit and the WHO Collaboratoring Centre for Reference and Research on Viral Hepatitis. The emphasis of the work will be on tissue culture, immunochemical and structural analysis of viruses. The appointment will be initially for up to 3 years and prior practical experience in virus work is essential.

2) for work with and cultivation of chlamydia. The appointment will be initially for one year.

Salary in the range: £4,958 — £5,810 plus £859 London Weighting according to experience.

Apply in writing giving full details of qualifications and experience and naming two referees to the Assistant Secretary by 19th November 1981. (9834)A

# UNIVERSITY OF THE WITWATERSRAND

Johannesburg

# DEPARTMENT OF BIOCHEMISTRY LECTURER

Applications are invited from suitably qualified persons, regardless of sex, religion, race, colour or national origin, for appointment to the above post. Applicants are expected to have a PhD or equivalent and appreciable research experience.

The salary range is as follows: Lecturer: R10,995 — R19,230 pa (£1 = R1,75 approx).

The initial notch and level of appointment will be determined in accordance with the qualifications and experience of the successful applicant.

Intending applicants should obtain the information sheet relating to this post from The South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar (Staffing), University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001, South Africa, with whom Applications should be lodged not later than 30 November 1981. (9826)A

### POSTDOCTORAL POSITION

available for Cell Biologist with strong background in biochemistry to investigate the structure and function of organelles involved in cell wall formation by plant cells and protoplasts. Some knowledge of plant tissue culture and/or electron microscopy is desirable. The position is available immediately for a one year term (renewable for a second year) at a salary of \$15,000.00 to \$18,000.00 depending on experience and qualifications. Some travel assistance is available.

Interested candidates should send curriculum vitae and 2 letters of recommendation to Dr L C Fowke, Department of Biology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0WO.

(NW026)A

### UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PHYSIOLOGY Faculty of Medicine and Dentistry

Applications are invited for the post of

# RESEARCH ASSOCIATE IB

to take part in a study of cardiovascular reflex responses in the systemic circulation and microcirculation. Applicants should have a good honours degree in physiology or related subjects.

Salary on the scale £5,285 to £7,700 with superannuation. Maximum starting salary £6,070. Post supported by the Medical Research Council for three years.

Further information from Dr J M Marshall, Physiology, 021-472 1301 ext 3458.

Applications (three copies) to Assistant Registrar, The Medical School, Birmingham B15 2TJ by 27th November 1981. Quote ref no RA/Phys/781. (9845)A

### FACULTY RESEARCH POSITION IN BIOCHEMISTRY

available at level of

### ASSISTANT PROFESSOR

Work involves biochemical studies obone regulation. Experience desir able in protein purification, cell cycl analysis, cell differentiation, immunochemistry, RIA membrane receptor studies, molecular genetics, o Vitamin D metabolism. Competitiv salary and exceptional opportunity is a well equipped, multidisciplinar laboratory.

Contact: D J Baylink, MD Department of Medicine, Roor 1501, Loma Linda University, Lom Linda, CA. 92350. Telephone 714/796-7311, extension 2171. A: Equal Opportunity/Affirmativ Action Employer. (NW024)A

### GEOPHYSICAL FLUID DYNAMICIST/PHYSICAL OCEANOGRAPHER

Applications are solicited for a junior faculty position in ocean physics or dynamics to begin in the academic year 1982-83. Areas of interest to the Department include analytical numerical and laboratory modeling of physical processes and phenomena in the sea.

Yale University is an equal opportunity/affirmative action employed and encourages women and members of minority groups to compete for this position.

Curriculum vitae, publications and the names of three or more referees should be sent by 3, December 1981 to: Robert B Gordon Chairman, Department of Geology and Geophysics, PO Box 6666, New Haven, CT06511. (NW1009)A

# EXPERIMENTAL POPULATION GENETICIST

with strong interest in eucaryotic ecology and evolution. PhI required. This is a tenure traciposition as Assistant/Associate Professor in Biology. Candidates will be evaluated for their potential to develop an outstanding research program with grant support and to interact with existing faculty in the genetics and ecology programs. Teaching will include upper and lower level courses in the area o specialty.

Application deadline: January 1 1982. Send CV, including reprints and three letters of reference to Chairperson, Search Committee Department of Biology, Box F, 20 Mueller Building, The Pennsylvanis State University, University Park PA 16802. An Equal Opportunity. Affirmative Action Employer.

(NW039)A

# **Experimental Therapeutics**

A new and progressive research group is to be formed within the Biology Department of G. D. Searle to study the Pharmacokinetics and therapeutic applications of new biological and chemical compounds. The establishment of this group complements the recent expansion of our Molecular Genetics and Chemistry Departments and is intended to provide information on the *in vivo* pharmacology of genetically engineered polypeptides and the metabolism of new chemical compounds at an early stage in their evaluation.

We are presently recruiting scientific staff for the three positions described below. Further scientific and technical vacancies are likely to become available as the work of the group expands.

# **Group Leader**

We seek an experienced and innovative scientist to head this new group. He or she will be a PhD with a first degree in a biological science or veterinary medicine and several years of post-doctoral experience in experimental pharmacokinetics or metabolism. The Group Leader will be responsible for establishing the group activities, maintaining high standards of research and creatively exploiting the potential for collaboration with other research groups. (Ref: B29)

**Biologist** 

An immediately post-doctoral scientist is required to assist the Group Leader with laboratory animal experimentation. Several years experience of *in vivo* pharmacology or experimental

metabolic studies would be advantageous. The successful candidate will be responsible for the design and execution of pharmacokinetic studies and will be assisted directly by highly trained animal technicians. (Ref: B41)

# **Biochemist**

A graduate in biochemistry is required to develop and apply chemical and biological assays to the study of natural and exogenous compounds in tissue fluids. His work will complement that of other analytical groups within the company and he will therefore primarily be concerned with the application of existing methodology to experimental work. Previous experience of automated techniques, HPLC analysis or clinical chemistry would be an advantage. (Ref: B42)

All the above positions carry competitive salaries commensurate with age and experience, and the Company offers 4 weeks' holiday a year, contributory pension fund, private medical scheme, subsidised cafeteria, and sports and social club.

Applicants, male or female, are invited to send a detailed CV or telephone for an application form from Miss D Wardman, Assistant Personnel Officer, Searle Research & Development, Lane End Road, High Wycombe, Bucks.

(Tel: High Wycombe 21124 ext 3374). Please quote appropriate reference.

(9829)A

### UNIVERSITY OF THE WEST INDIES Trinidad

Applications are invited for the post of RESEARCH

RESEARCH FELLOW/JUNIOR RESEARCH FELLOW

IN THE SEISMIC RESEARCH UNIT

Candidates should be well qualified in Geophysics, Geology or a related field. A doctorate and experience in operating seismograph networks is desirable. Salary scales (under review): Research Fellow TT\$29,784 — TT\$43,752 pa. Junior Research Fellow TT\$24,156 — TT\$26,484 pa. (£1 sterling = TT\$4.27). FSSU. Unfurnished accommodation or housing allowance. Family passages. Study and Travel Grant.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent as soon as possible to the Secretary, University of the West Indies, St Augustine, Trinidad. Applicants resident in UK should also send 1 copy to the Committee for International Copperation in Higher Education, The British Council, Higher Education Division, 90/91 Tottenham Court Road, London W1P 0DT. Further details are available from either address. (9824)A

# THE INSTITUTE FOR ADVANCED STUDY

will have several openings for members in theoretical physics and astrophysics for the academic year 1982-83. The positions are at a post-doctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of elementary particles, mathematical physics, astro-physics, plasma physics, general relativity and statistical mechanics. Preference is given to candidates who have received their PhD within the last year or two.

Postdoctoral members frequently collaborate with each other, with faculty members at the Institute or Princeton University, and with researchers at other institutions.

Appointments ae usually for no more than two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are encouraged to apply.

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW1006)A UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH WELSH PLANT BREEDING STATION

Aplications are invited for the post of

# SCIENTIFIC OFFICER (I) HIGHER SCIENTIFIC OFFICER (I)

in the Station's Grassland Agronomy Department. This is a new post created under the Welsh Hills and Uplands R&D programme. The successful candidate will join the Department's exiting Hills and Uplands team but will carry out most of the field work at Pwllpeiran Experimental Husbandry Farm.

Candidates should possess a First or upper Second Class honours degree in agricultural, biological or soil science with at least two years relevant post graduate experience for appointment as HSO. Preference will be given to candidates with a PhD and a Knowledge of hill farming conditions.

Pay Scales: (S0) £5,176 - £6,964 (HSO) £6,530 - £8,589. Starting Salary according to qualifications and experience. Noncontributory pension scheme but male employees aged 18 or over contribute 1 ½ % to Widows and Orphans Fund.

Further particulars and application forms are available from The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed. Closing Date for applications is 27 November 1981. (Quote reference 68).

SCHOOL OF MEDICINE DEPARTMENT OF MICROBIOLOGY AND IMMUNOLOGY

# **POSTDOCTORAL POSITION**

is available immediately to study gene expression and recombination in RNA viruses of eucaryotes. Research emphasizes the molecular biology of defective interfering virus particles and their role in virus persistence.

Studies include cloning and sequencing of viral genome deletions and regulation of viral polymerase activities. Salary is equivalent to NIH

Send applications, including curriculum vitae and names of three references, to Dr Jacques Perrault, Box 8093, Department of Microbiology and Immunology, Washington University School of Medicine, St Louis, Missouri 63110 USA. Equal Opportunity/Affirmative Action Employer M/F/H. (NW020)A

# YALE UNIVERSITY DEPARTMENT OF GEOLOGY AND GEOPHYSICS

Applications are solicited for a faculty position in solid earth geophysics to begin in the academic year 1982-83. Areas of interest to the Department include seismology, exploration geophysics, mechanical and physical properties of rocks and minerals, geomagnetism, and tectonophysics.

Yale University is an equal opportunity/affirmative action employer and encourages women and members of minority groups to compete for this position.

Curriculum vitae, publications and the names of three or more referees should be sent by 31 December 1981 to Robert B Gordon, Chairman, Department of Geology and Geophysics, PO Box 6666, New Haven CT 06511. (NW1010)A (NW1010)A

# Medicinal **Chemist**

Pfizer Central Research is part of a multi-national organisation engaged in the research, development, manufacture and marketing of a wide range of human medicinal and animal health products. Located at Sandwich, on the Kent Coast, are our modern, well equipped facilities where about 500 scientists and supporting staff are engaged in the discovery and development of novel compounds for use in human and veterinary medicines.

Recent expansion of our project portfolio has created an opportunity for an innovative Medicinal Chemist, with 3-5 years' post-doctoral experience of research in the pharmaceutical industry, to lead a small team of chemists on a new project to discover substances which reverse certain aspects of microbial pathogenicity. He/she will collaborate closely with a recently established team of biologists already working in this area.

The person we seek will have originality, drive and a desire to remain in basic research for many years. There is ample opportunity for the successful candidate to gain promotion to positions of higher scientific management.

The person matching our needs can expect a very competitive starting salary with good bonus potential. Pension and death benefit schemes are in operation and there is generous assistance with relocation

expenses. Flexible hours are worked and the social/recreational facilities are first-class.

Applications, giving details of qualifications, age, experience, etc., will be treated in strictest confidence and should be sent to: D. W. Sells, Personnel Manager, Pfizer Central Research, Sandwich, Kent.

(9818)A

# **Royal Postgraduate Medical School**

(University of London)

Department of Clinical Pharmacology in collaboration with Imperial Chemicals Industries Limited Monoclonal Antibodies to Cytochrome(s) P-450

A graduate with a good honours degree or equivalent experience, in biochemistry or pharmacology is required to join a Joint Research Scheme project between the Department of Clinical Pharmacology, Royal Postgraduate Medical School and Imperial Chemical Industries Limited (Central Toxicology Laboratory and Corporate Biosciences Group). The aim of the project is to produce monoclonal antibodies to cytochrome(s) P-450 from human and rodent liver. These antibodies will be used for the characterisation of cytochromes and in their purification. The successful applicant will be involved in helping in the characterisation of the antibodies with respect to their reactions with the cytochromes P-450.

The person appointed will join an existing team at the Royal Postgraduate Medical School consisting of analytical chemists, pharmacologists and an immunologist. The appointment is for 2 years with a starting salary between £5,451 and £6,556 depending on

Application forms and further details are available from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS, quoting reference number 20/211.

Closing date for applications 20 November 1981.

# Senior Pathologist

# Pharmaceutical Research

This is a senior and important appointment within the expanding UK Research Centre of a well-known international pharmaceutical company

Reporting to the Director of Toxicology and Pathology, the successful candidate will be responsible for the identification, interpretation and evaluation of morphological and pathological changes in animal tissues, as part of the safety evaluation of new

Ideally candidates should be veterinary pathologists, but the appointment could be open to well-experienced comparative animal pathologists who do not possess formal academic qualifi-cations. The company is prepared to structure the post according to the background interests and potential of the person appointed for someone whose interests and experience to date are primarily scientific, it could be as a specialist histopathologist; for someone with appropriate qualifications, experience and management skills, it could be as Head of Pathology - leading a small, well experienced multidisciplinary team.

A highly competitive salary will be negotiable individually, according to qualifications and experience. Other benefits include non-contributory life assurance and pension schemes, and generous relocation expenses if required

Please write in confidence for an application form, or phone if you would like to discuss the appointment further before applying.

### THE DISTILLERS **COMPANY LIMITED ASSISTANT SCIENTIST**

The Food Group of the Distillers Company Limited require an Assistant Scientist for work in the Spirit Yeast Fermentation Laboratory of their Yeast Research Department, Menstrie, Clackmannanshire.

Applicants should have a HNC qualification in chemistry, preferably with 2 or 3 years laboratory ex-perience in the use of fermentation or biochemical techniques and including the handling of gas liquid chromatography equipment. Applications from candidates possessing qualifications other than HNC will not be considered further. The person appointed would be directly responsible to the Microbial Biochemist in charge and would assist him in research projects as well as in routine laboratory work with eventual responsibility for day to-day laboratory operations.

An application form can be obtained by writing to: The Yeast Research Manager,

The Distillers Company Limited, Food Group,

Research Department, MENSTRIE.

Clackmannanshire FK11 7ES. Closing date for applications November 20th, 1981. (9816) (9816)A

# LINIVERSITY OF SASKATCHEWAN

DEPARTMENT OF **GEOLOGICAL SCIENCES** 

Applications are invited for a vacant tenurable position in

# **ENGINEERING** GEOLOGY/GEOPHYSICS

Applicants should be qualified to teach undergraduate and graduate courses and to conduct research in engineering geology. A background in structural geology may be appropriate. Well-equipped facilities are available for research in rock mechanics, fluid flow through porous media, acoustic and electrical properties of rocks, and permafrost. Rank and salary commensurate with qualifications and experience.

Send applications, detailed personal résumé including the names of at least three referees, and other supporting data to Dr W G E Caldwell, Head, Department of Geological Sciences, University of Saskatchewan, Saskatoon, Saskatchewan S7N 0WO.

Please note: until November 15, 1981 consideration will be given only to applicants who are Canadians or landed immigrants, after that date all applications will be considered.

(NW033)A

# **UCLA SCHOOL OF MEDICINE** DEPARTMENT OF MICROBIOLOGY AND **IMMUNOLOGY**

Applications are solicited for a tenure track faculty position in the area of

VIRAL IMMUNOLOGY

at the rank of Assistant Professor Outstanding applicants possessing a doctoral degree, postdoctoral experience and a strong commitment to developing an independent research program are sought. Applicant must be inte-rested in studying host response to viral diseases using immunological approaches. Applicant must be well trained in both conceptual and technological aspects of modern immunology, virology and possibly molecular biology and must show a strong promise of independent research capability. Responsibilities include participation in the departmental teaching of medical, dental and/or graduate students as well as possibly developing a graduate course in viral immunology. Please submit curriculum vitae, current research interest, list of publications and names of references. Nominations of outstanding candidates are also

Debi P. Nayak, BVSc, PhD Professor and

Jack G. Stevens, DVM, PhD Professor and Chairman Department of Microbiology and Immunology, UCLA School of Medicine, Los Angeles, CA 90024. UCLA is an equal opportunity and affirmative action employer.
(NW044)A

### **UNIVERSITY OF** LIVERPOOL CHAIR OF SMALL ANIMAL STUDIES

Applications are invited for the newly established Chair of Small Animal Studies. The person appointed will be expected to encourage academic staff of the Small Animal Hospital actively to pursue specialist clinical interests and research in addition to clinical teaching duties. It would be an advantage if the successful applicant were an authority in a branch of small animal internal medicine but other disciplines are not excluded.

The salary will be not less than £16,480 per annum.

Applications (12 copies) together with the names of three referees, should be received not later than 11th December, 1981, by the Registrar, The University, PO Box 147, Liver-pool L69 3BX, from whom further particulars may be obtained. (Candidates overseas who wish to do so, may send only one copy by airmail). Quote ref RV/899/N.

# AWARDS

# Nominations are invited for the 1982 Rosenstiel Award in Oceanographic Science

This award, which is administered on behalf of the Rosenstiel School of Marine and Atmospheric Science (RSMAS), University of Miami, recognizes outstanding contributions to marine science, including oceanographically relevant aspects of atmospheric science, and fundamental developments in ocean engineering. The award consists of a cash prize, currently \$5,000, and a medal. The recipient of the award will be invited to spend a week at RSMAS for discussions with faculty and students. The award will be presented at a banquet at that time.

To accommodate the multidisciplinary value of oceanographic science, the award recognizes, on a rotating basis, achievements in four broad disciplinary areas. In 1982 the emphasized discipline will be marine geology and geophysics. The achievements recognized may consist of contributions towards the development of ocean science in general, or of more focussed-individual research or recognized impact on our understanding of the marine environment.

Nominations for the 1982 award for outstanding achievement in marine geology and geophysics should be directed to the Interium Dean, Warren J. Wisby, Rosensteil School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, Florida 33149, before March 15, 1982. Nominations should include a brief justification together with relevant references, and a c.v. if possible. The selection panel would especially welcome nominations of outstanding younger scientists whose early contributions suggest a continued role of leadership in the field.

Previous recipients of the award in Marine Geology and Geophysics have been Edward Ringwood, Kenneth Emery, and John Sclater.

# **FELLOWSHIPS**

The Max-Planck-Institute for Psychiatry, Department of Neurochemistry, in Munich, Federal Republic of Germany, offers a

POSTDOCTORAL RESEARCH FELLOWSHIP for Research in Molecular Neurobiology

Applications are invited for a 2-5 year postdoctoral appointment to begin as early as January 1982. Research involves the isolation of neuron-specific cDNA probes as tools for the study of nervous system development. Experience with DNA sequencing, recombinant DNA techniques and DNA-RNA hybridization analysis is essential. Approximately salary is 40,000 to 50,000 DM.

Applications should be sent to Dr. Louis De Gennaro, Yale University School of Medicine, Dept. of Pharmacology, P.O. Box 3333, 333 Cedar St., New Haven CT 06510, USA, or to Dr. H. Thoenen, Max-Planck-Institute for Psychiatry, 8033
Martinsried, Federal Republic of Germany. (NW022)E

### **POSTDOCTORAL FELLOWSHIPS IN ZOOLOGY**

The Department of Zoology at the University of Florida announces one or two postdoctoral research positions starting August 1982. The duties of the appointments, (\$15,000/12 months, renewable for a second year), will be to establish an effective research project in comparative, ecological or evolutionary zoology. The Department will provide a list of faculty and their recent publications upon request. Candidates should submit the names of three referees, curriculum vitae, abstract of dissertation, and a proposal of their intended research, which should include a statement of the appropriateness of the University of Florida for the research. Direct in-

quiries and submit applications to:
Dr. Brian K. McNab Chairman, Postdoctoral Search Committee,
Department of Zoology, University of Florida, Gainesville FL

32611 904/392-1178.
Application deadline 1 February 1982.
An Equal Opportunity / Affirmative Action Employer.

(NW040)E

# **UNIVERSITY OF NEWCASTLE UPON TYNE FELLOWSHIPS**

Applications are invited for the following Fellowships, tenable for two years from 1 October 1982, from persons who have shown themselves able to carry out original research. The value of each Fellowship is £6,070 in the first year and £6,475 in the second year.

# SIR JAMES KNOTT **FELLOWSHIPS**

Two Fellowships available in any Faculty (normally awarded to graduates of other Universities) LORD ADAMS **FELLOWSHIP** 

One Fellowship available in any Faculty

preference will be given to candidates who, through family, residence or education, are connected with the former County of Cumberland or whose proposed research has connections with, or will be of benefit to that County.

Further particulars and application forms (which must be returned by 31 December 1981) may be obtained from the Registrar (Fellowships), University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU. (9833)E 7RII

# THE BRITISH COLUMBIA **TERRY FOX TRAINING CENTRE**

### announces initiation of a FELLOWSHIP PROGRAM

for outstanding MDs or PhDs seeking further training in laboratory or clinical aspects of modern cancer research. Preference will be given to Canadian citizens or Landed Immigrants. Duration of support will be from one to three years depending on previous training and goals. The Program will support a maximum of four trainees at any given time. Research projects are available in: Hematology, cytogenetics, tumor immunology, virology, molecular biology, endocrinology, chemotherapy, radiobiology, epidemiology, and environmental car-cinogenesis. MDs may also proceed towards a PhD in Experimental Pathology, Genetics, Microbiology, or Biophysics. Yearly stipend for 1982: approximately \$20,000 plus \$1,500 for each year post-MD or \$1,200 for each year post-PhD.

Applications must be received by May 1st and December 1st of each year (starting December 1st, 1981), and should be sent with curriculum vitae and three references to: Allen C Eaves, MD, PhD, Co-Ordinator, Terry Fox Training Centre, BC Cancer Research Centre and Cancer Control Agency of BC, 601 West 10th Avenue, Vancouver, BC Canada Avenue, V5Z1L3. (NW023)E

## THOMAS C USHER RESEARCH FELLOWSHIPS AND STUDENTSHIPS TENABLE AT THE MRC LABORATORY OF **MOLECULAR BIOLOGY** IN CAMBRIDGE

Mr Thomas C Usher of Toronto, Ontario, has provided funds for the support of Fellowships and Studentships open to scientists of any nationality, including British, who wish to come and do research in molecular biology at this Laboratory. These will be of three kinds:

- 1) Long-term fellowships for period of 6 months to two years, subject to review after the first year, and renewable for further periods. Fellows will also be eligible for Visiting Fellowships at Clare Hall and Darwin College.
- 2) Short-term fellowships for any period of up to 6 months, for collaboration of scientists in the United Kingdom or abroad with members of the MRC Laboratory on specific
- 3) Studentships for graduate students for three years, subject to annual review.

Fellows stipends will be paid at current British University scales for teaching staff, normally within the range of £5,505 to £11,575 per annum (pay award pending); the actual stipend paid depending on age and experience. Reasonable travelling expenses for Fellows and their families from their normal place of residence to Cambridge and return expenses at the termination of the Fellowship will be paid.

Graduate students will be paid at current rates for state studentships which now rise from £2,090 per annum at age 21 to £3,150 at age 27. Their University and College fees will also be paid.

Awards of Fellowships and Studentships are conditional on acceptance of the applicant by one of research groups in the Laboratory.

Applications should be addressed to Dr M F Perutz, MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK and be accompanied by a curriculum vitae, the names of at least two referees, and for categories (1) and (2) only, a list of publications and a research proposal of between 300 and 1,000 words. Applications should reach Dr Perutz by 16th April 1982. (9825)E

# Spiders

E.O. Wilson: Let me remind you that people everywhere, a large percent of the population, at a very early age have already developed a deep horror at the sight of snakes or spiders with nothing more than gentle nudging from their parents, if that. Yet, in spite of the fact that parents constantly reinforce their children against going near electric sockets, automobiles, knives and the like, phobias against such objects rarely develop.

Marvin Harris: Let's go back again to the possibility that these phobias are genetically programmed — which I'm willing to grant. The overwhelming bulk of the socially conditioned response repertories of different human societies consists, by your own admission, of culturally determined rather than genetically determined traits. Then it seems to me that when one offers a cogent culturological explanation of these photos

# New surf ces for cell culture

Now you can choose the most suitable microcarrier for your culture

Cytodex microcarriers bring new opportunities to

- routine and experimental cell culture
- production of viruses, interferon and other cell products
- in vitro studies on differentiation and metabolism

Cytodex 1

The microcarrier proven to be effective for growing more than 100 different cell types.

Especially developed for better yields of viruses and cell products. Retains all the advantages of Cytodex 1 with the added benefit of new charged groups necessary for cell attachment localized only on the surface of the microcarriers.

Cytodex 3 The latest concept in microcarriers. The stable collagen surface gives improved attachment and yields of many cell types, especially those normally difficult to grow in culture. Enzyme digestion of the surface gives improved recovery and viability of harvested cells.

Make the most of your cell cultures. For more information on how Cytodex microcarriers give you new opportunities in cell culture contact us today.

1981. 47 figures. XXII, 630 pages. (Handbook of Experimental Pharmacology, Vol.57) Cloth DM 340,-; approx. US\$154.60 Prepublication price Cloth DM 272,-; approx. US\$ ISBN 3-540-10623-5

Contents: Introduction to Cell Growth: Growth in Size and DNA Replication. - Survival and Growth Requirements of Nontransformed Cells. - Epidermal Growth Factor. - The Platelet-Derived Growth Factor. - Somatomedin: Physiological Control and Effects on Cell Proliferation. - Glucocorticoid Modulation of Cell Proliferation. Proteases as Growth Factors. - Nerve Growth Factor. The Role of Cold Insoluble Globulin (Plasma Fibronectin) in Cell Adhesion in Vitro. - Membrane-Derived Inhibitory Factors. - Diffusible Factors in Tissues Cultures. Hemopoietic Colony Stimulating Factors. - Inhibition of Hematopoietic Cell Proliferation. - Inducers and Inhibitors of Leukemic Cell Differentiation in Culture. -Angiogenesis Factor(s). - Growth of Human Tumors in Culture. - The Chalones. - Author Index. - Subject Index.

The fundamental intracellular and environmental factors that control proliferation and differentiation in mammalian cells are examined in this volume. The authors of the articles, all leading workers in the field, provide a broad survey of the present state-of the-art in this rapidly expanding field. They take into consideration both stimulatory and inhibitory factors, and interdigitate our knowledge of growth factors indentified in tissue cultures with those effective in the animal as a whole.

# Why not enjoy microscopy from the word go. With the LEITZ HM-LUX 3.

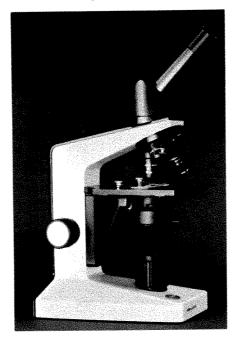

This robust instrument has been developed specially for natural science teaching and for private use. At a surprisingly low price it opens up even to the layman the world of microscopy without problems.

Leitz objectives and eyepieces ensure above-average optical performance at a field-of-view diameter of 18 mm.

The novel accommodation drive reduces the controls of the instrument practically to a single element for the coarse and fine focusing of the image. Damage to the objectives or to the specimens owing to impact is prevented even when the accommodation drive is operated without care. It is therefore possible to focus without any risk of damage. Even for the beginner in microscopy focusing will become an subconscious act within a very short time so that he can devote his full attention to the image and to its interpretation.

The basic low-cost outfit with microscope mirror and monocular tube can be extended by the user very simply into the much more convenient

version with built-in low-voltage illuminator, binocular tube, and object guide as soon as required. When used with

the 100/1.25 OIL objective the LETTZ HM-LUX 3 offers the highest optical microscopic magnification. With suitable equipment, umstained specimens can be observed in darkground or in phase contrast.

If you would like to hear about other advantages of the LETTZ HM-LUX 3, please send us the coupon duly completed. We look forward to contacting

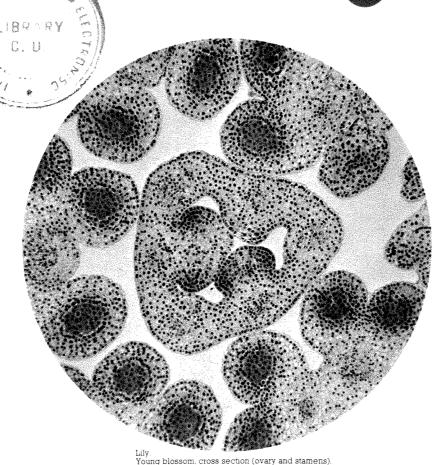

Circle No. 01 on Reader Enquiry Card.

☐ I should like to know more about the LETTZ HM-LUX 3 and would be grateful for your detailed prospectus. I should like to make an appointment with the LEITZ consultant in the near future.

Name/Address: Establishment: Please send us this coupon or simply write to Information Service, No 409.
Ernst Leitz Wetzlar GmbH, PO.B. 2020, D-6330 Wetzlar I, Telephone: (0 64 41) 29 1.

Leitz means precision. World wide.

From detection of monoclonal antibodies, through specificity determination and purification from ascites, BRL has the reagents to enhance all phases of your hybridoma-based research.

A complete system for the screening of hybridomas that secrete mouse immunoglobulins. The kit includes: β-galactosidase conjugated sheep anti-mouse IgG F(ab')₂, p-nitrophenyl-β-D-galactoside as substrate, and complete protocol for use. In this enzyme-linked immunosorbant assay (ELISA), the second-antibody reagent has several advantages over alkaline phosphatase- and peroxidase-coupled antibodies: β-galactosidase is highly purified, and has a high specific activity. It is not present in most eukaryotic cells, and low background values are encountered when screening for cell surface antigens. Thus, sensitivity is enhanced. Also, p-nitrophenyl-β-D-galactoside does not show the potential carcinogenicity of other substrates used in ELISAs.

**BRL 9502 SA** 

# *Immunoprecipitin*

Immunoprecipitin is formalin-fixed Staph A cells for the selective adsorption of IgG immunoglobulins. It specifically and tightly binds to the Fc portion of an IgG molecule and therefore will precipitate antigen-antibody com-

BRL® Immunoprecipitin is subjected to rigorous quality control assays to assure you a reliable high quality product. Its features include: High specificity and affinity for IgG immunoglobulins; 1 mg of Immunoprecipitin will bind  $\geq 8~\mu g$  purified rabbit IgG  $\blacksquare$  High stability for at least four months when stored at 4°C ■ Complete elution of the antigen from the absorbant for both analytical and preparative purposes • Complete protocol describing the removal of loosely bound proteins to reduce contamination of antigen by bacterial proteins

**BRL 9321 SA** 

# Protein A Agarose

BRL® Protein A Agarose is an affinity matrix prepared by covalently coupling purified Protein A to agarose beads. Protein A binds to the Fc portion of IgG molecules without interfering with ability of the immunoglobulin to bind antigen. This specificity permits the single-step purification of IgG antibodies and some IgM and IgD classes. BRI® Protein A Agarose is distinguished by: ■ Stability over a wide pH range (2 to 11) ■ Compatability with strong denaturants like guanidine hydrochloride and urea ■ Actual lot analysis to determine the amount of Protein A bound to the gel (1.8 to 2.5 mg/ml of gel), and the binding capacity for human IgG (8 to 10 mg/ml of gel)

**BRL 5918 SA** 

BRL invites inquiries on product specifications and performance. Please do not hesitate to call our Technical Services staff at 800-638-4045. To place an order, contact our Customer Services Department at 800-638-8992.

# Amersham offers 3'-end labelling kits which give you:

# Convenience

All the reagents needed to label DNA in one kit.

# **Flexibility**

Amersham's kits are available with or without cordycepin 5'- $[\alpha^{-32}P]$ triphosphate for maximum economy of label.

# **Efficiency**

Labels all 3 types of 3'-end – protruding, blunt and recessed.

# **Simplicity**

Few pipetting steps. Easy to handle volumes.

# Quality

All batches of our kit are subject to rigorous quality control. A copy of the autoradiograph, obtained after labelling the standard DNA provided in a standard reaction, is supplied with each kit.

**PB.4025** Non-radioactive reagents  $+250\mu\text{Ci}$  cordycepin 5'- $[\alpha$ - $^{32}\text{P}]$  triphosphate, sufficient for 5 standard 3'-end labelling reactions.

**PB.4100** Non-radioactive reagents + 1mCi cordycepin 5'- $[\alpha$ - $^{32}P]$  triphosphate, sufficient for 20 standard 3'-end labelling reactions.

**N.4005** Non-radioactive reagents only – sufficient for 5 standard 3'-end labelling reactions.

**N.4020** Non-radioactive reagents only – sufficient for 20 standard 3'-end labelling reactions.

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

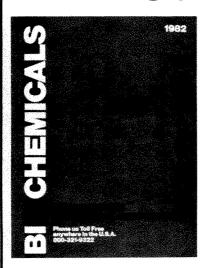

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according. to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

The new 1982 USB Catalog is ready, with over 5,000 biochemicals listed and available for prompt delivery. So you can rest assured that you'll get just what you need, when you need it.

Best of all, it includes the very latest products in categories such as Amino Acids, Peptides, pl Marker Kits, Buffers, Enzymes, Co-Enzymes, Nucleic Acids, Nucleotides, Biological Test Diets, Tetrazolium Salts and Crosslinking Reagents.

Second best of all, it's free. Call or write for your copy today. It's all the help you need.

We're part of the solution. **United States Biochemical Corporation**

### Contents

Probability and Statistics; Segregation of Alleles; Assortment of Non-Alleles; Linkage, Recombination and Mapping; Linkage, Recombination and Mapping; Mating Systems; Appendix 1 — Mean and Variance of a Binomial Distribution; Appendix 2 — Estimation of a Parameter by the Method of Maximum Likelihood; Appendix 3 — Extensions of the Method of Maximum Likelihood; Appendix 4 — Comparative Efficiency of Matings for Detection and Measuring Linkage: Comparative Efficiency of Matings for Detecting and Measuring Linkage; Appendix 5 — the Fibonacci Sequence; Appendix 6 — Systems of Mating; Appendix 7 — Numbers of Mating and Numbers of Mice per Mating; Appendix 8 — Nomenclature; Appendix 9 — Record Keeping; Appendix 10 — Mouseroom Layout and Procedures; Glossary of Signs;

This book is a primer and reference on This book is a primer and reference of probability, segregation, assortment, linkage and mating systems for biomedical scientists who breed and use genetically defined laboratory animals for research.

Literature Cited: Index

It is organised so as to be useful to novices' and 'experts' alike. The former will find an orderly development of the probability aspects of transmission tests, segregation analysis, allelism tests, independence analysis, anienth tests, independent tests, linkage analysis and mapping. They will see how to design genetic experiments to yield data which can be analysed and they will also find a clear exposition of the theoretical consequences of various breeding systems which will enable them to make rational choices as to the kinds of animals to use in their own

Experts will find that the most experts will find that the most frequently used formulae needed for estimating various genetic parameters and their random sampling variances are assembled in tables or are clearly set forth in the text and that the extensive table of contents and detailed index will enable them to find the necessary formulae quickly.

# What case for basic research?

Researchers threatened by the budgetary process in the United States are preaching the virtues of basic research. But even Dr Frank Press's argument will not wash. What should be done?

The budgetary process in the United States, always confused, is this year causing more than the usual havoc. There is now a serious danger that, whatever is decided, needless damage will be done to important scientific institutions. For although it is customary that the Administration's authority to conduct government business at the beginning of the financial year stems from a continuing and temporary resolution by Congress, the sequence of events this year will provide the new President's men with a licence to spread alarm and despondency among the agencies they control. Some, to their shame, seem to have leaped at the opportunity. But even when the heads of government agencies have been resolute and far-sighted, research managers have been forced to think what has hitherto been unthinkable. The general mood of alarm has spread widely through that part of the American research establishment supported directly by the Administration. Further afield, those who will be looking for research grants from the grant-making agencies are despondent or are making eyes at the Department of Defense, one of the few agencies of the United States government certain to have more to spend. Whatever damage is done by whatever budget is eventually agreed, the mere process of getting something settled is now certain to leave a scar on the research enterprise. Sooner rather than later, something must be done to put things right.

# **Budget**

Since the beginning of the year, Congress has been faced with no fewer than three versions of the budget for the year that started on 1 October, beginning with President Carter's valedictory budget which must in retrospect be read as his declaration of how well-heeled everybody would have been if only they had voted for him in sufficient numbers. The framework of the new budget appeared only in March, together with President Reagan's proposals for reductions in the rates of income and corporation taxes that, in what is almost certain to prove a pyrrhic victory, the President carried through Congress early in the summer. Left alone, Congress might well have lived up to form and enacted some kind of budget authority in the usual wild legislative scramble between Thanksgiving Day and Christmas. The trouble, which became apparent during August, is that the March budget coupled with the tax cuts would require the United States to run a deficit of between \$60,000 million and \$100,000 million in the twelve months to next October. Seeking to retain some semblance of Republican virtue in the management of its affairs, the Administration accordingly proposed in September a 12 per cent cut in the discretionary expenditure of all its agencies except the Department of Defense (whose increased budget was cut by \$3,000 million in August) and the National Aeronautics and Space Administration (whose spending is reduced by only 6 per

Congress is now trapped in a familiar dilemma. The Administration is right to argue that deficit financing will only sustain inflation and prolong the period when interest rates remain high, but agreeing to the cuts proposed will be unpopular with the voters (who will be going to the polls only a year from now). So members of Congress are cheerfully denying the President the 12 per cent cut he asks for, preferring that he rather than they should incur the odium of appearing mean, which is what will happen if he should veto the inflated appropriations bills. The only quick way out of the impasse that has been created

is that the Administration should agree to a postponement of its plans for the MX missile and the B1 bomber, against which both houses of Congress have raised cogent objections, in which case the inflationary implications of the present budget will seem less threatening. That, however, would be a climb-down for the Administration which is unlikely to be undertaken lightly or quickly. In the meantime, the agony in the research community will continue.

Rumours abound of what the consequences will be. Will it be necessary to close whole laboratories? The Brookhaven National Laboratory is potentially a casualty if its new accelerator is abandoned (see Nature 5 November, p.3). And if it turns out that the National Aeronautics and Space Administration has no funds left over from the ill-starred space shuttle, can it make sense to keep the Jet Propulsion Laboratory alive? Thus, almost casually, the fate of powerful components of the American research enterprise are loudly discussed. No wonder that those concerned are making discreet enquiries of the Pentagon about the military tasks they might take on. Not all establishments are as fortunate, however. The laboratories of the Bureau of Drugs whose members have been told their jobs are not of the highest priority (see page 101) will be kept on tenterhooks for many months to come. Elsewhere, even in laboratories whose usefulness is widely acclaimed, research directors are compelled by sheer prudence to draw up lists of people whose jobs may have to go on the insubstantial grounds that, with more than a tenth of the financial year already gone, and while the possibility remains that they may have to reduce expenditure by an eighth before the financial year is over, preparing to fire people soon is more important than the prosecution of an imaginative research programme. This is no way in which to deal with intellectual enterprises. So much, both Congress and the Administration must be given clearly to understand.

# Message

But how? What kind of message is likely to carry weight with an Administration apparently less sensitive than its predecessors to intellectual interests and a Congress preoccupied, as always, with the problems of its own reelection? Dr Frank Press's colloquium at the National Academy of Sciences two weeks ago (see Nature 5 November, p.4) was a first attempt at putting the case for basic research to the Administration, but is unlikely to carry much weight. For the plain truth is that in the United States, as in Britain for the past several years, basic research as such has come to be regarded as effete, a kind of luxury. Everybody knows that the pursuit of a deeper understanding of natural phenomena gives great pleasure to those directly engaged in it, while even the most cynical legislators are prepared to hail the award of a Nobel prize to a fellow-countryman as a mark of their own percipience (which is naturally magnified a hundredfold if the prizewinner should be a constituent). To do them justice, however, legislators are also properly preoccupied with the larger question of how they can be held by their constituents or anybody else to have behaved responsibly if they condone inflation and thus, by extension, the erosion of the value of property, the undermining of established institutions and the setting of a trend towards the fly-by-night. Dr Press's "consensus statement" made a seemly acknowledgement of the United States Administration's economic problems. It went disastrously awry in asking that if government support for

science and technology had to be reduced, basic research should be given priority over development and demonstration. Even the Majority Leader in the Senate, Senator Howard Baker, has helped in the past few days to breathe new life into the most spectacular demonstration of all—the technically antiquated fast reactor at Clinch River. It is, however, unlikely that Senator Baker did not know of Dr Press's colloquium. More probably, he did not care.

# Incorrigibility

So are the Senator Bakers of this world incorrigible? Or is it that those engaged creatively in basic research are indefinitely and repeatedly dispensable? These questions are not easily dealt with. Most politicians will accurately calculate that if the population of those now engaged on basic research is so eager to continue with that pursuit, the recruitment of a substitute should be relatively easy once it again becomes affordable. Moreover, the calculation is entirely correct. There will never be a shortage of people willing to deepen understanding if offered the chance. What is in question is their capacity to do so in a vacuum. The experience since the Second World War of a variety of nation-states selfconscious about their conduct of basic science has shown convincingly that success depends on the ease with which relatively young people can hit the ground running, as the appropriately American idiom has it. This in turn entails that the social function of senior and often distinguished researchers is to serve as a means by which young people can make a quick start. Newton acknowledged his debt to the giants on whose shoulders he stood; but the fabric of scholarship is such that even the shoulders of pygmies (relative to, say, Copernicus) are literally infinitely better than nothing. The first and the most important defence of basic research, in the United States and elsewhere, is that the process is cumulative. Not to have shoulders of any kind to stand on would spell some end-point for the research community which, for the whole of the past three decades, has been the chief source of intellectual innovation anywhere.

Unfortunately, the most immediate implications of this truth are that all basic research is equally valuable as a means of launching young and innovative people on the natural world. In present circumstances, that is probably as far from being the case in the United States as elsewhere. Indeed, the plurality of possible sources for the support of basic research of which the United States can still boast, and the freedom accorded by universities and other academic institutions to those who can recruit funds, ensures that even inward looking projects win an honourable place in the research enterprise. It would have been more persuasive, of Senator Baker but also of the United States Administration, if Dr Press's consensus document had squarely promised that the academic community would itself arrange that young people would always have durable shoulders on which to stand. Briefly, if the National Academy of Sciences wishes, as it should, to persuade the Administration to acknowledge the importance of continuity in basic science, it must also itself take on some responsibility for defining the circumstances in which basic research should be supported.

### Default

By default, the academy's consensus statement last week fell back on the weaker argument that industry would be robbed of the skilled people it needs if basic research is deprived of the funds to which it has grown accustomed. This line of argument is persuasive among academics. Unfortunately, neither the government nor industry, the supposed beneficiary, is likely to be impressed. Each of the sceptical but interested parties is fully aware that, for several years, the computer industry in the United States has been forced to manage without a sufficient supply of trained engineering graduates from the universities and that it has nevertheless managed creditably to look even Japanese competition in the face. Who would say that more support for basic science in the past decade would have remedied this state of affairs? And who would hold that academic institutions are necessarily the places at which the people best qualified to design

the next generation of integrated circuits, or the next elaboration of sophisticated software systems, should be trained? Most probably, even those who contributed to Dr Press's consensus document last week would judge this to be too pointed a question, too particular. The potential benefits of basic research, the riposte would go, by definition lie in fields that cannot as yet be defined. Yet Congress, the Administration and the throng of taxpayers and voters increasingly hag-ridden by inflation are understandably concerned with solving the unsolved problems that can be foreseen. Is it too much to ask that the basic research community should take time off from its usual preoccupation with the design of research-grant proposals to pay some attention to the preparation of young people for the modern world?

In such circumstances, the hope (still buoyant among even American academics) that industry will somehow step in to make good the deficiencies of federal spending is uncharacteristically unrealistic. Industry at present contributes only a small part of the cost of basic research carried out at universities and other research laboratories not directly controlled by government or by itself. For various reasons, not always calculations about the best way of paying less tax, corporations will no doubt seem more generous in the years ahead. (The public rhetoric will help.) Yet there is not the slightest hope that industry would be able — even if it were willing - to meet the full cost of reinvigorating engineering education in the United States. Moreover, there is the strongest reason why the basic research community, essentially the academic research community, should resist such a development — a university's chief responsibility is to its students and not to those who may eventually become its students' employers. It follows that the cost of university education, and of the research that keeps that education alive, should fall either on the students or on the community to which they belong. Third parties have no place. Paradoxically, then, the basic research community can best serve the needs of American industry by remaining as far as possible financially independent of it.

# Change

Thus it is that the basic research community is faced with a version of the dilemma with which Congress and the Administration are confronted. How, when the cost of carrying on without change is insupportable but when change as such is unacceptable, is the essence of an enterprise, or of an institution or even of a community (say, a nation-state) to be preserved intact? Congress is denying the Administration the budget cuts for which it asks because Congress cannot accept that its constituents' expectations of the modern world should be disappointed. The Administration is (so far, at least) inflexible on its defence budget because it dare not risk the frustration of its election promises. Both parties to this non-bargain know, however, that their failure to reach an accommodation is a recipe for disaster - one that would touch all sections of the community, not merely that concerned with basic research. The participants in Dr Press's colloquium might with advantage have taken hold of that point more directly. It is not merely their government's problem but theirs. Within their own parish, they should also have had the wit to recognize that among the chickens that have come home to roost are some born of academics' own firm belief that basic research is an occupational right (and that graduate students exist for the education of undergraduates); that the curriculum that has grown up in no more disciplined a way than Topsy is nevertheless sacrosanct; and that the time has come if not for change then for adaptation.

Fortunately, the American system of basic research is still so much more varied than any other that much of it is likely to survive the hard times ahead. The research community is right to protest at the wayward incidence of the latest round of budget cuts, and at the way in which they arbitrarily affect those projects that can most easily be cut. It would also be within its rights to complain that both the Administration and Congress have undervalued its contribution to the health, wealth and adaptability of the community in which it is embedded. But it cannot hope not to have change itself.

# Closure threat at FDA laboratories

# Drug testing facilities given low priority

Washington

The Food and Drug Administration (FDA) seems to be playing cat and mouse with the 500 members of the staff of its drug research laboratories in south-east and south-west Washington. Last month, as the Reagan Administration's budget problems became apparent, the FDA management raised the prospect that its three drug investigation laboratories might be shut. At the same time, all members of staff were advised that they should ensure that their career record forms (SF171) were complete by the end of October. This is a familiar preparation for dismissal. Although the Senate Appropriations Committee has now decided that the emergency cut of \$40 million in FDA's budget should be trimmed by \$6 million, members of staff have the impression that the laboratories' days are numbered.

FDA's response to last month's budgetary problems seems to have been unusually panicky. Senior officials of the administration were given 24 hours in which to define a package of economies amounting to 20 per cent of the budget. At a meeting on 16 October in the auditorium of FDA's Humphrey Building, more than 200 scientists were told that the investigation had shown that the Bureau of Drugs could dispense with its divisions of drug biology and of drug chemistry and the biopharmaceutics laboratory. It had already been decided that the national centre for antibiotic analysis, supported chiefly by fees from manufacturers with products to test, will be disbanded, largely on the grounds that its work could be carried out by private laboratories.

Anxiety about the future of the laboratories stems from the form of words used at the meeting on 16 October by Dr Richard Terselic, deputy director of the Bureau of Drugs. Terselic is reported to have told his audience that on several occasions in the past two or three years, studies of the consequences of large budget cuts had repeatedly shown the laboratories to be dispensable. Asked what would happen if the cut required of FDA was more like 5 per cent than 20 per cent, he is reported to have said that "if you have decided that A is less important than B. . . there is a pressure in the system" that will make the less important activity vulnerable in future years.

A spokesman for FDA confirmed last week that the continuation of the work of the laboratories "has been identified as a low-priority area". He added that in the light of the action by the Senate Appropriations Committee, it was not now likely that the laboratories would be closed during the present financial year (which began on 1 October).

FDA's drug investigation laboratories occupy a central role in its regulation of new drugs. Their functions include the checking of manufacturers' claims for the safety of new materials and an assessment of the efficacy of materials proposed for medicinal use. Among the laboratories' claims on public attention is that they were the source of the first warnings of the dangers of thalidomide in the late 1950s.

Members of the laboratories claim that

closure would compel the Bureau of Drugs to rely on post-marketing surveillance for the independent assessment of the efficacy of new drugs. It seems likely that such a departure from present practice would raise hackles in Congress. A letter-writing campaign by those concerned has been begun, while earlier this week it seemed likely that Congressman Albert Gore, chairman of the oversight subcommittee of the House of Representatives Committee on Science and Technology, would try to get to the bottom of FDA's intentions.

The outcome of a mandatory meeting of all the laboratory staff called for Tuesday this week is not yet apparent.

# UK universities plan to fire staff

British universities are still in a state of confusion over how to economize to meet the cuts in their grants. A major worry is still whether compensation to academics who lose their jobs will cost the universities more than savings in lost salaries. The answer will depend on how much extra money the government is willing to make available specifically for redundancy payments.

The Committee of Vice-Chancellors and Principals, which expects the first redundancies to be announced within a few weeks, now says that the matter is urgent. Last week it asked the University Grants Committee (UGC), which distributes government money among universities, to announce the terms under which it will compensate universities for redundancy payments.

The vice-chancellors' committee has provided the UGC with its own recommendations for the minimum compensation to which redundant academics should be entitled. Its scheme is intended to ensure fair treatment, especially for those academics whose contracts of employment do not give them security of tenure. Those with tenure, however, are likely to fight for higher compensation through the courts, making it still impossible to calculate the total redundancy bill. The best estimate remains that made in the summer of about £250 million.

The vice-chancellors' compensation scheme is based on that for civil servants. It is divided into three age categories — above 55 years, 50–55 years and below 50 years. Under the scheme, academics aged 55 years and over would be entitled to compensation broadly in line with the existing premature retirement scheme which provides a lump sum and an early pension. For example, an academic aged 55 years with 30 years' service and a salary of £15,410 would receive £23,115 as a lump sum and £7,705 index-linked annual pension. Total cost to the university would be £39,989.

The vice-chancellors say that existing

early retirement terms for academics aged 50-55 years are unfair. Accordingly, they recommend an additional lump sum payment to compensate for up to five years' loss of pension rights. Hence a redundant academic aged 50 with 25 years of service and an annual salary of £15,410 would receive a lump payment of £21,566 in addition to an index-linked pension of £6,742 a year and a further lump sum of £20,226. The total cost to the university would be £72,150.

Academics under 50 years of age would be entitled to a lump sum severance payment in addition to the normal lump sum and pension payable after retirement age. The total extra cost to the university would be only the lump sum payment. This would mean that an academic made redundant at age 40 years with 15 years of service and an annual salary of £11,425 would receive £23,800 on redundancy, a £6,426 lump sum and an annual pension of £2,142 after normal retirement age. The extra cost to the university would be £23,800.

The vice-chancellors' committee hopes that the UGC will adopt its scheme when deciding how to compensate universities for redundancy payments. But precisely how much money the UGC can make available remains uncertain. The £20 million already earmarked will almost certainly be inadequate, but much will depend on when the bills come in.

The vice-chancellors' scheme, however, is being given short shrift by the Association of University Teachers (AUT), the academics' trade union, which refuses to discuss the possibility of compulsory redundancy. The AUT believes that universities should make economies only through early retirement, frozen posts and non-payroll savings. It is adding its voice to requests that the government should spread the cuts over five instead of three years.

The AUT's threat to start legal proceedings at the first hint of compulsory redundancy, even before names are

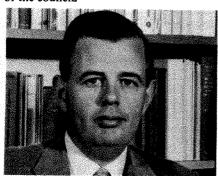

named, has already had an effect. Pressure from the local union branch at the University of Aston in Birmingham persuaded the university to postpone compulsory redundancies at least until the next academic year. Local pressure also persuaded the University of Keele to withdraw its notification of 300 impending redundancies to the Department of Employment. Other universities have also decided to delay job losses in an attempt to avoid being the first to be dragged through the courts. A handful are also apparently planning not to balance their books for several years. Their policy of living on borrowed money perhaps for three or four years is favoured by the AUT.

# Science research council

# Paying a price

The capacity of the Science and Engineering Research Council to make research grants to British academics is likely to be impaired, in the year immediately ahead, because of the overspending by the council's Science Board, in the financial year that ended on 31 March. One of the ironies of this situation, described in the council's annual report for 1980–81, published last week, is that the chairman of the offending board, Professor John Kingman, has now succeeded Sir Geoffrey Allen as chairman of the council.

Kingman - poacher to gamekeeper?

According to the report, the council's allocation of funds to the science board will be reduced in the current year, while the board must repay to its master the outstanding amount of its over-spending.

The over-spending occurred, according to Professor Kingman, when the council decided to adopt a more bullish attitude to its spending to avoid falling into the trap of having money that it had not spent taken away by the government. In the event, it over-stepped the mark and received a sharp rap over the knuckles from the House of Commons Public Accounts Committee and a warning not to over-spend again.

Professor Kingman is confident that the council can do better this year. He expects spending to be within 0.15 per cent of the budget, the margin allowed by the Treasury, which he nevertheless complains is too narrow and would never be expected

in industry.

Although the science board over-spent by only a small fraction of its annual budget (£64.4 million in 1980-81), the effect on its activities has been marked. During 1980-81, the announcement of some research grants to universities had to be delayed for lack of funds. The repayments this year and next will also not help the board meet its future commitments, about one-third of which are to research and teaching in universities.

According to the annual report, support for university research, a third of which is channelled through the science board, had to be cut somewhat during 1980-81. Matters this year are complicated by the cut in university income which is increasing pressure on the council's research grants.

But the report, for which Sir Geoffrey Allen is responsible, says that spending on research grants should soon be restored at least to the level of recent years. Nevertheless, it is unlikely that the council will be able to support all grant applications given its highest merit grading of alpha.

The council, in 1980-82, spent £56.5 million on research grants out of its total budget of £207.8 million. A few more grants were awarded than in the previous year but the increase was due almost entirely to an unusually large number of requests for continuing support in some areas. A total of 1,983 research grants, valued at £74.5 million, were recommended in 1980-81 compared with 2,412 awarded in 1979-80.

Judy Redfearn

# New man in

Within a week of the resignation of the president and director-general of the French research agency, the Centre National de la Recherche Scientifique (CNRS) (Nature 5 November, p.3), a new director-general has been appointed: the long-time socialist party member M. Jean-Jacques Payan, a 46-year-old mathematician, and president of the University of Grenoble I.

The presidency of CNRS remains unfilled, although constitutionally the president has to help select the directorgeneral. However, the director-general bears the main management load, and so the filling of this post was considered the more urgent.

M. Payan's first task will be to reestablish confidence in the CNRS management, to represent CNRS in the national colloquium on science and technology (which takes place in January) and to consider the reorganization of CNRS — particularly taking into account the strongly expressed wish of the engineers, technicians and administrators of the many CNRS laboratories to play a more significant role in policy-making.

**Robert Walgate** 

# German energy policy

# The future unclear

Count Otto Lambsdorff, the West German economics minister, was balanced on a precarious political tight-rope last week, when he announced the governing coalition's energy policy for the next decade. Judging by his description of the "third continuation of the energy programme" (the second continuation was in 1977), he had little money, little energy and few plans. Or at least he had few plans he would admit to, for fear of rocking the coalition.

For example, to prepare the third continuation, Lambsdorff had asked several German economic institutes to make forecasts of energy needs and production. Usually a government will give guideline projections for the total economy in such circumstances; but Lambsdorff could not or would not provide them. And while the institutes clearly recommended a quadrupling of nuclear power generation by 1995 (from 3.7 per cent of primary energy to 17 per cent), Lambsdorff would only commit himself to the remark that "nuclear energy must provide an increasing percentage of baseload electricity'

Several factors lie behind this imprecision — strong local opposition within the Social Democratic Party (SDP), one of the coalition partners, to the expansion of nuclear power; the possible retirement of Chancellor Schmidt through ill-health before the 1984 general elections, complicated by the lack of an obvious successor; and the forthcoming fight in the local government elections next year, when SDP must present as united a front as it can.

Were it not for these political complications, the government would no doubt like to commit itself firmly to cheap nuclear power, which - behind the scenes - it sees as essential for maintaining the competitiveness of German industry. But if nuclear power is to be cheap, it must be plentiful, goes the calculation. A new German 1,300-MW pressurized water nuclear power station would cost nearly twice as much in Germany as in France, a German manufacturer claimed recently. According to the company, this is largely because the French companies were "tooled up" for long production runs, and environmental regulations and delays are less extreme in France. At best, nuclear power might contribute 25 per cent of German electricity by the mid-1980s, compared with France's 70 per cent by 1990, the company estimated.

Nevetheless, it is not good politics in SDP at present to be seen to be a strong supporter of nuclear power, in spite of the fact that there seems recently to have been a change of mood among the German public. Germany's strong dependence on oil and gas keeps domestic energy prices high, and the nuclear industry's claims that

nuclear power can be cheap is winning adherents.

Last week, however, Lambsdorff did commit himself to one change of policy. Like all Western ministers, he needs to save money during the world recession. Some of it will come from the coal industry—heavily subsidized in Germany to make its price competitive with the imported variety. These subsidies will be reduced, and cheaper coal imported. Germany should also shift away from burning "brown coal", and use it to provide chemical feedstocks. The missing energy would be provided by nuclear power.

The German government would not be deflected from its commitment to a DM 10,000 million (£2,400 million) deal with the Soviet Union to provide Western Europe with natural gas through an overland pipeline from Siberia, Lambsdorff said last week. The deal would provide West Germany with around 12,000 million cubic metres a year, 30 per cent of its natural gas requirements. A large fraction of this gas will be used to produce electricity. Natural gas power stations at present produce 50 per cent more electricity in Germany than do nuclear stations.

Robert Walgate

# **UK** Government Chemist

# New broom

The Laboratory of the Government Chemist, for long a respected but retiring establishment, may yet emerge from the shadows. For Dr Ronald Coleman, who will take over as Government Chemist when Dr Harold Egan retires at the end of December, intends that the laboratory should play a more central part in British science.

The laboratory, which employs about 400 people, provides a wide range of analytical services, mainly for the public sector. Thus it is concerned with the estimation of additives in foods and the characterization of oil-spill samples for correlation with suspected sources of pollution. Although supported by the Department of Industry, the laboratory is paid for specific services by government departments and local authorities. The laboratory has few dealings with the private sector and its research is largely that required to keep abreast of new analytical techniques.

Dr Coleman plans to change all this. He intends to broaden the remit of the laboratory, to make it "more open" and to

# Asian mycotoxins

In the story "Yellow rain: Waiting for data", Nature 22 October p.598, it was mistakenly stated that a sample of vegetation had been taken from Laos for analysis. In fact it was taken from Kampuchea.

Coleman - talking change

forge links with both industry and the universities.

Dr Coleman would like the laboratory to "have a finger in more pies". In its analytical work he would like the laboratory to branch out into work on surface chemistry and on-line instrumentation. Mr Coleman himself has just been given responsibility for biotechnology in the Biotechnology Directorate set up last month, but the laboratory's role in this new venture remains to be determined.

Dr Coleman is also ambitiously planning coordinated programmes with industry, hoping that the laboratory could contribute technical expertise and industry the necessary funds. He has already talked to five interested industrial companies.

Dr Coleman points to his varied experience. At present he is deputy director of the National Physical Laboratory, but his career began with five years in the glass industry. His twenty-year spell with the United Kingdom Atomic Energy Authority involved work with nuclear energy, forensic science, geochemistry and biotechnology.

Isobel Collins

# Polish science

# Academy for change

Warsau

Self-governance, the move towards "social control" of all sectors of public life, will undoubtedly bring considerable changes in the structure of Polish research planning. In particular, there have been vocal demands, coming especially from the scientists' lobby within the free trade union Solidarity, for parity of status between the universities and other higher educational institutions, the Academy of Sciences and its subsidiary institutes, and the institutes belonging to the production ministries (including the ministries of agriculture, fisheries and mining).

Funding tends to be less generous in the academy institutes than in those belonging to the ministries, many of which, it has been suggested, were founded more for reasons of prestige than for any real

research need. Although with Poland's newly-admitted unemployment problems—particularly among young graduates—closures are unlikely, a thorough-going reconsideration of the pattern of research is expected. Any moves from the top to start making changes would, however, run the risk of conflicting with the demand—expressed by the recent Solidarity congress—that scientists should have more say in choosing their own pesearch topics.

Another Solidarity recommendation calls for the elimination of the barriers between the academy and the rest of the academic community. During the past few years the various academy institutes have become havens for young academics prevented from taking teaching posts for political reasons, and one of the changes suggested by Solidarity would be to allow scientists working at academy institutes to lecture to university students.

At the same time, there is considerable unrest both inside and outside Solidarity about the present anomalous status of the academy as a quasi-ministry, with its academic secretary responsible not to the academy but directly to the prime minister. A spirited debate, on this and other points, is expected when the general assembly of the academy meets in December, chiefly to debate the proposed new legislation on the academy.

A new bill on higher education is already on its way to becoming law, and (following the protests and strike-threats of last September) it now has the basic consent of the academic community. Vera Rich

# Californian Medflies

# **Brief armistice**

Sacramento, California

Aerial spraying against the infestation of the Mediterranean fruit fly, now much curtailed for the duration of what Californians laughably call the winter, is likely to be resumed in earnest in the spring. But Mr Richard Rominger, director of the state Department of Food and Agriculture, told his Advisory Committee on Thursday last week that enough insect traps have been installed in the northern counties for next year's campaign to be effective.

Meanwhile, fruit farmers in Florida and Texas as well as California are more concerned with an unexpected consequence of the Californian campaign against the Medfly. The practice of fumigating fruit from affected areas of California with ethylene dibromide has raised environmental objections in Japan, one of the chief markets for United States fruit exports, and has also drawn attention to widespread use of ethylene dibromide for fumigating fruit from Florida and Texas (where other pests, such as the Mexican fruit fly, are common). Mr Rominger was hoping, last week, that the Japanese authorities would now accept as safe the Californian requirement that fumigated fruit should contain no more than 130 parts per billion of ethylene dibromide, but he had yet to persuade longshoremen in the United States that fumigated fruit could be handled safely.

Nobody knows the economic cost of the "abrupt interruption of the channels of trade" caused by the infestation and the consequent fumigation, but Mr Rominger thinks it exceeds by an order of magnitude the direct cost of aerial spraying to California, put at \$50 million for this year.

The reasons why California was caught napping by this year's events are now becoming clear. Operations against the Medfly are directed from the state's laboratory at Los Gatos, between San Jose and Santa Cruz to the south of San Francisco Bay. Medflies were first recognized in Southern California in June 1980, but that infestation was successfully dealt with by the release of sterile male flies, as had been the 1975 infestation near Los Angeles.

The importance of the nearly simultaneous outbreak in Santa Clara county (just north of Los Gatos) was appreciated only much later, partly because insect traps were more thinly spread but also because the complete life-cycle of the insect (22 days in tropical conditions) seems to vary enormously from one microclimate to another and may be as long as 77 days in the northern counties.

The density of traps in the northern counties at risk has now been increased to 50 per square mile, and adult Medflies are still sporadically being caught in them. Members of the laboratory's staff recall with anguish the early months of this year, when they were "desperate" for supplies of sterile males to release into the field. More than 10,000 million were used before aerial spraying was begun in mid-July.

The belief that supplies of supposedly sterile larvae from Peru were in reality fertile seems not to be supported by the evidence the laboratory has collected. The staff says that the Peruvian supplies of sterile flies were, however, poor in quality — some consignments yielded only 10 per cent of viable adult flies. The fertile females of Peruvian origin recognized in the field in June this year (on the basis of a fluorescent dye) may well have derived from larvae contaminating a Peruvian consignment after the bulk of it had been irradiated.

The present hiatus in the campaign against the Medfly has not stilled political recriminations, directed chiefly at Governor Edmund G. (Jerry) Brown. Mr Brown's stand against the aerial spraying of a carbohydrate bait laden with malathion, in the face of technical advice to the contrary, is widely resented by his opponents in the state legislature as well as by farmers' organizations and many agriculturalists.

Thus Mr Richard Niellson, a member of the State Senate, is concerned that the incident will have permanently damaged California's reputation as a reliable supplier. He, among other members of the legislature, is planning to use the budgetary process now beginning to see that proper provision is made for the war against the Medfly in 1982 and succeeding years. But this year's experience, when the Red Cross centres set up to deal with casualties among the urban population of California were hardly used, has, Mr Niellson says, seen a decline of the "Rachel Carson syndrome" among the Californian electorate.

Mr Rominger, who with some of his technical advisers had threatened to resign if aerial spraying was not begun, hopes that the 17-member "pest prevention task force" due to hold its second meeting this Monday will insulate pest protection from politics. The committee is intended to present the governor and the state legislature with a general strategy for protection against all insect pests by the beginning of 1982. Meanwhile, the state will have to decide what to do about the 700 claims for civil damage which have been lodged, while inspection stations at the Californian border are likely to reappear.

For most Californians, the events of the past months are likely to prove cathartic. Next season, farmers (who are not prevented from ground spraying with malathion and more powerful insecticides) will take more active steps to protect their crops. The state as a whole seems to have recognized the economic importance of its agricultural industry, worth \$14,000 million a year. And people in urban areas have been left with a lasting impression of helicopter visitations at night (when the air is still), with their searchlights illuminating suburban gardens. "This is what it must have been like in Vietnam" said one whose white Volkswagen is still spattered with grey malathion bait.

# **Nuclear Structure Facility**

# Nylon slip shows

Water in the nylon insulating links of the charging system of the Nuclear Structure Facility, a 30 million volt tandem Van de Graaff accelerator for nuclear physicists under construction in the United Kindom at Daresbury Laboratory in Cheshire, is now blamed for delays which will put the commissioning of the machine back at least to spring 1982.

A new material, Torlon, will have to be used in place of the monocast nylon in the pioneering machine, which is the highest voltage Van de Graaff yet designed. The nylon, Daresbury physicists found to their cost, contained a small proportion of water. This did not affect the insulating properties of the nylon at room temperature, but the conductivity rose a hundred-fold between 20°C and 35°C, the physicists discovered. So when the "laddertron" — a charging belt like a tank track made of alternating links of nylon and aluminium to carry charge up to the high-voltage

terminal — was first tested at full scale, and friction raised its temperature to 35°C, it failed.

Torlon, an American-made material, was not available when the accelerator was first designed, but in a test section of laddertron it has proved its superiority to the monocast nylon. The whole laddertron will now be rebuilt with Torlon.

However, the problems of the accelerator are not over yet. Unfortunately monocast nylon was used for other parts of the accelerator. Now the laddertron problems appear to have been solved, these too may have to be replaced.

Moreover, early next year the accelerator tube — the evacuated metal and ceramic tube down which the beam of nuclei must pass — will be installed and tested. And unless the Daresbury team are lucky for once, this too may cause delays. At Oak Ridge National Laboratory in the United States, problems with a similar tube set a 25 million volt machine back by a year — and even now the laboratory may have to be content with 20 million volts rather than the design figure.

Nevertheless the delays at Daresbury have had one bonus. All the experiments will be ready in time for the first beam, despite a low rate of funding which implied that only the bare minimum of experiments would have been possible earlier.

Robert Walgate

# Caltech

# Kellogg birthday

Pasadena

The Kellogg Radiation Laboratory at the California Institute of Technology combined its celebrations of its fiftieth anniversary last week with the dedication of a new custom built Megavolt accelerator and a seventieth birthday party for Professor William Fowler, the third director of the laboratory. Fowler, always ebullient, stole the show, but the laboratory was at pains to emphasize that it has been clever enough to equip itself with a new accelerator, albeit in the MeV range, when high-energy physics laboratories are wondering how long their GeV machines will be able to function.

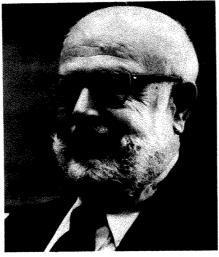

The Kellogg Laboratory is the West Coast's chief monument to R. A. Millikan, the president of the California Institute of Technology when the laboratory was first formed. Millikan's original prospectus included the use of high-energy radiation in the treatment of cancer. During the Second World War, the laboratory played an important part in the determination of nuclear cross-sections needed for the Manhattan Project. Since then, it has been principally concerned with the application of nuclear physics to other fields, astrophysics in particular.

The new accelerator, represented last week by its external yellow tank and christened as if it were a sea-going object, has been designed for high ion current and voltage stability. It will be used, among other things, for the laboratory measurement of nuclear cross-sections relevant to the processes of nucleogenesis which are at present uncertain.

But Dr Barbara H. Cooper also outlined a scheme for using the accelerator as a charge spectrometer for checking the claim by William Firbank and his colleagues at Stanford University that electric charges exist which are a fraction of the electronic charge, and which might represent free quarks. Preliminary estimates suggest that by using an argon beam for sputtering free atoms from solid surfaces, it should be possible to evaporate one of the small niobium spheres used in the Firbank experiments in about an hour, and that the tandem accelerator should be capable of detecting one fractionally charged particle in as many as 10<sup>18</sup> niobium atoms.

While astrophysical problems will remain a central part of the Kellogg Laboratory's programme, diversification is also in the air. This is the spirit in which the laboratory is involved with studies of the release of radon-222 as possible predictors of major earthquakes, just now a matter of public interest in California.

According to Professor Thomas A. Tombrello, two of the network of radon monitors maintained by the laboratory near the San Andreas Fault had revealed a substantial increase of radon evolution since the early weeks of August. The

W.A. Fowler at seventy.

increased rate of evolution (which continues) has been closely correlated in time even though the two instruments are separated by 100 kilometres, and is said to resemble that which preceded the 1979 earthquake of magnitude 6.7. That event was marked by a transition from the normal compressive stress across the surface rocks of the San Andreas Fault to an extension — thought to stimulate radon release — but also by a cessation of radon release in the days immediately before the earthquake.

Professor Tombrello prudently avoided prediction last week, saying only that "sometimes, perhaps in 25 or 50 years, one

of these events is going to be a precursor of a major earthquake". He complained, however, that financial support for earthquake studies of this kind in California was less than that in China and Japan. "Since 10 million people would be affected by a major earthquake, it would be worth putting a little money into it."

# Albanian development

# Hoxha looks ahead

Albania, too, has an urgent need of science and technology, according to party leader Enver Hoxha's speech to the congress of the Albanian Workers' Party last week. But although the "deepening of the technical scientific revolution" has encouraged teaching and research, practice lags behind precept. Mr Hoxha said that the most obvious need is for a mechanism for the gradual transfer of innovation on a "wider front" aimed at the "radical" transformation of technology and production.

Mr Hoxha's criticism came in a speech praising the achievements of Albania's system of education, scientific education in particular. He drew particular attention to Albanian achievements in hydroelectric and railway engineering, the sinking of deep wells, geological prospecting, stockbreeding and the machine tool industry. He emphasized that these had been accomplished by the Albanian people "relying completely on their own forces" justification of the country's long standing isolation policy. Although the Academy of Sciences is still the major centre for scientific research in Albania, Mr Hoxha said that the Committee for Science and Technology set up this year was an important instrument for the "better direction and organization" of science.

The targets for the Albanian 1981–85 five-year plan are more ambitious than in any previous quinquennium. Industry will receive some 46 per cent of the total investment budget, with special emphasis on mining and energy resources. Oil extraction is expected to rise by some 60 per cent, coal by 48 per cent and that of proved mineral resources (chromium, copper and iron nickel) from 30 to 200 per cent. The chemical industry will be considerably expanded, with an expected rise in production of some 65 per cent by 1985.

Mr Hoxha was at pains to say that these targets are "scientifically based and fully achievable". Furthermore, to provide the necessary personnel, special attention will be given to higher education. Student admissions during the next five years will rise by 45 per cent, new courses will be introduced and there will be a considerable expansion of postgraduate courses. Publication of "political, scientific, technical and artistic" books will rise by one million copies over the previous quinquennium and educational cinema, radio and television will be expanded. Vera Rich

# Hoyle on evolution

The serious part of the Kellogg symposium provided Sir Fred Hoyle with an opportunity for a moderate (and self-critical) statement of his case for disbelieving conventional views about the evolution of the Universe, the "big bang" among them. Hoyle has been associated with the Kellogg laboratory since his collaboration in the mid-1950s with W.A. Fowler and the two Burbidges (Margaret and Geoffrey), now known as the gang of four, on the problem of nucleogenesis.

Hoyle said last week that, although content in the mid-1960s to give the supposed connection between the microwave background radiation and the big bang a "good run for its money", he had now lost patience with this approach. Two of his reasons involve the origin of life - the calculated time since the origin of the Universe of 10,000 million years or so is not enough to account for the evolution of living forms, while adiabatic expansion of the Universe would have been inimical to the evolution of highly ordered forms. But Hoyle also said that new evidence in support of the big-bang hypothesis was emerging only slowly. Yet "when people are on the right track, new facts emerge quickly". Hoyle said he would change his view if it turned out that neutrinos have a mass of between 20 and 30 electron volts.

The essence of his argument last week was that the information content of the higher forms of life is represented by the number 1040,000 - representing the specificity with which some 2,000 genes, each of which might be chosen from 1020 nucleotide sequences of the appropriate length, might be defined. Evolutionary processes would, Hoyle said, require several Hubble times to yield such a result. The chance that higher life forms might have emerged in this way is comparable with the chance that "a tornado sweeping through a junk-yard might assemble a Boeing 747 from the materials therein".

Hoyle acknowledged that steadystate theories of cosmologies, of which he was one of the chief exponents in the 1950s, are not now tenable because of the evidence for evolutionary galactic and stellar processes. But the big-bang view is similarly not tenable because of the way in which it implies the degradation of information. Of adherents of biological evolution, Hoyle said he was at a loss to understand "biologists' widespread compulsion to deny what seems to me to be obvious".

# Good as gold

SIR — In the current debate on a gold standard the stumbling block is the fundamentally wrong premise in the quest to fix a price. It is not possible to fix a price for gold in terms of any existing currency. Far better to consider not a price but a value. Gold has a value as a medium of exchange, in other words as a currency. Consider the implications of using gold as money.

Assume all gold reserves minted into coins of standard weight and fineness. At a given date equate the number of coins so available with the figures used internationally in representing the price of goods and services in circulation. One coin will be found to equate to many hundreds of dollars.

Now start using only gold coins to pay for goods and services. Note the dramatic fall in the numbers on the price tickets (the first skirmish in the war on inflation). Continue to mint all newly-won gold into the standard coins. Charge the weight of gold going into industry or jewellery at the value of the equivalent number of coins. Paychecks would of course come down accordingly. Cheques and all paper transactions could be continued, but only against deposits in the equivalent number of coins. Gold money thus on deposit would pay interest whereas gold now in the bank does not.

The result would be a stable currency and stability of values. The gold-producing countries wold not get any richer (you can't eat gold) whereas countries with exports of commodities or manufactures, instead of suffering from "lack of hard currencies" would find their products are as good as gold.

This desirable state of affairs would continue as long as the supply of coins was adequate to satisfy the needs of international commerce. However, the rate of increase of the net worth of the world is historically greater than the rate of increase of gold production and is likely to remain so. In this situation the remedy would be to have a periodic revaluation of the value of the coin. Clearly this value is going to tend upwards and, as a concomitant, the numbers on the price tickets will go down — the very reverse of inflation. Gold thus produces capital gains.

The return to gold usage (rather than a gold standard) would provide a solution to currency and exchange problems and, since the money supply would be finite, a cure for inflation and a clear directive for monetary policy.

# Harsh words

Sir — Your comments on Dr Rupert Sheldrake's book A New Science of Life (Nature 24 September, p.245) are very harsh. One can hardly pretend that our current understanding of development and its genetic control is adequate. We should not even believe that it is oriented in the right direction. The concept of morphogenetic fields is neither unscientific nor without support from some distinguished embryologists. If the same concept is extended to all aggregations of matter, animate or otherwise, it may be considered as a bold, hazardous, foolhardy or

unwarranted generalization, depending on one's attitude towards new thought. Just a hundred years ago if somebody suggested that the sequence of nucleotides in DNA constitutes the information required to make a fly, a frog or a man from a small bit of cytoplasm it would have been dismissed as preposterous. If there is no obvious way of testing experimentally Dr Sheldrake's hypothesis of formative causation, it does not preclude its possibility in the future.

Many embryological theories depend on recourse to morphogenetic fields in spite of the recent progress in genetics and molecular biology. No real progress can be made in understanding the importance of these fields without identifying the nature of the variables along the gradients. Perhaps the only measurable variable to which the origin of a gradient can be traced is the concentration of diffusing substances. Positional information which adds a new dimension to the concentration of diffusing substances is also now accepted as a fundamental mechanism of morphogenesis. However, even these powerful theoretical tools have not successfully accounted for any single embryological event. In fact it would be preposterous to assume that development of complex organisms can be explained solely on the basis of the current theoretical platform on which molecular biology stands. Recourse to new conceptual framework and unconventional mechanisms is imperative to understanding complex biological processes such as morphogenesis.

# Page charges

Sir - Frank Close's review of high-energy physics journals in Nature 1 October (p.369) reveals a misconception that may be widespread enough to warrant correction in public. I refer to his statement that "in times of financial stringency European authors are often unable to publish there [in Physical Review] as a result of page charges". The fact is that the page charge system, not only in Physical Review (including Physical Review Letters) but in all journals published by the American Institute of Physics, is a voluntary one. Payment of page charges is requested. but acceptance of a contribution is not conditioned by whether page charges are paid. The only effect of nonpayment is a delay in publication; and even that is not imposed on papers in Physical Review Letters, or on the newly instituted rapid communications section in Physical Review.

I hope I will not be misconstrued as urging authors to submit papers to our journals and not honour the page charges when they are in a position to pay them. I do not even mean to solicit papers for the journals. Those costs that are not met by page charges have to be made up from higher subscription costs for persons and institutions that are not members of the various societies; and we are as concerned as anyone else over the effects of ever higher costs to libraries. I do feel, however, that it is important that the true state of affairs be completely understood.

# Belgium's power

SIR — Your recent article on nuclear safety in Belgium (*Nature* 24 September, p.249) prompts me to explain some points about Belgium's approach to nuclear power.

First, the nuclear power station licensing procedure in Belgium involves two stages: (1) on approval of all planning and logistical aspects and the safety guidelines, permission is granted for construction to start and (2) after subsequent safety analysis and approval, permission is granted to put the power station into operation.

During plant construction there is continued liaison between the public authorities, technical experts, suppliers and the station owner, to ensure that all safety aspects are in line with the Belgian regulations. This process involves the exchange of about 2,000 questions and answers, and has the advantage that the most modern safety innovations are incorporated into Belgian nuclear power stations at an early stage. This could clearly not happen if the design had to be frozen at the time of the construction permit.

Given the long construction period required for such plants, this procedure eliminates the problem of premature technological obsolescence. It is also interesting to note that Belgium is the only country to submit nuclear power station designs for approval to a committee of international (EEC) experts.

Second, the question of the number of specialists officially appointed to deal with nuclear safety was somewhat misrepresented in your article. Belgian law confers supervisory authority for the nuclear sector to a state-approved inspection organization, Vinçotte. Other official government bodies, however, exercise ultimate control in this field. So in fact there are many more than the 17 Vinçotte inspectors involved in supervising the safety of the Belgian nuclear power stations.

On the other hand, although it is true that the International Atomic Energy Agency has cited the figure of 50 experts as a standard force to deal with nuclear safety in a country like Belgium, the responsibilities of such a force would include operational control, regulatory missions, evacuation plans and so on, in addition to overseeing general safety precautions. In Belgium these aspects are not neglected, but are properly dealt with by the governmental bodies and technical experts mentioned above, (including the "Commission for questions concerning radiation").

Finally, with respect to the threatened strike by the employees of Vincotte, their qualms did not stem from questions of power plant operations, but rather from the uncertainty of their career prospects.

So to summarize, (1) the procedure followed by the utilities before putting a nuclear power plant in operation strictly follows Belgian law—the strictest in the world, according to IAEA. And (2) the force of experts and inspectors in charge of safety supervision is perfectly adequate, both in number and competence, and is in a position to enforce the nuclear safety regulations, as it has indeed done (nuclear power stations have been operating in Belgium for 20 years).

# NEWS AND VIEWS

# High energy physics grows tenfold

from Robert Walgate

THE first ever controlled collisions of fundamental particles at centre of mass energies of over 540 GeV — ten times higher than previously achieved, and an energy at which spectacular physics is expected — are beginning to be observed at the new proton antiproton collider at the European centre for nuclear research (CERN), even before the machine is out of the hands of its constructors.

"We take data while the engineers take their coffee breaks", Carlo Rubbia, leader of one of the two experiments now in place, said last week. Rubbia - a well-loved Italian-American maverick of high-energy physics - in fact proposed the whole idea of the collider, in which bunches of protons at 270 GeV collide with oppositely moving bunches of antiprotons. The proposal came in, in a report at the 1976 Aachen neutrino conference titled "Looking for the intermediate vector boson with existing accelerators". He has not been slow to reap the rewards now the machine is in place. So far his experiment (UA1) has recorded some 20,000 events, but no intermediate vector boson.

On the other side of the collider (which is in fact the super proton synchrotron modified to take colliding beams) is experiment UA5, headed by Dr John Rushbrooke of the University of Cambridge with professors Klaus Bockmann of Bonn, Jacques Lemonne of Brussels and Gösta Eksborg of Stockholm and their groups. UA5 has taken 1,500 pictures (one of which appears below) with another 10,000 expected in the next month.

The events of UA1 and UA5 together are only the first scratching of the surface of physics at these exalted energies, but already there are some indications of what may or may not be expected.

The physics needs to be seen in relation to two quite separate classes of prediction. On the one hand, there are some peculiar data from cosmic ray experiments — a handful of "Centauro" events and others — which indicate that there may be a substantial change in physics at energies close to, or perhaps somewhat above, the energies of the new collider. On the other, there are the predictions of the Salam-Weinberg unified gauge theory of the weak and electromagnetic interactions, which has been well-tested at lower energies in electron and neutrino scattering experiments.

This theory is the backbone of most current attempts at a "grand unification" of all the forces, and it predicts the existence of three intermediate vector bosons (Z°, W+, and W-) at masses of around 80 GeV. These should be created at collider energies, and should be seen to decay as predicted by the theory. The theory also predicts new scalar particles called Higgs' particles, but the masses of generally speaking, these are. undetermined and the particles may or may not turn up in collider experiments.

So far there are no data from CERN on the intermediate vector bosons, but that is not unexpected. Estimates suggest that the IVBs will only be produced in small numbers, and too few events have been collected so far to expect one among them. Finding the bosons also depends on increasing the luminosity of the collider (effectively the number of collision per second per unit interaction cross section) by orders of magnitude beyond those presently being reached at CERN. Design luminosity was  $10^{30} \, \text{s}^{-1} \, \text{cm}^2$ ; the present achievement is  $2 \times 10^{25}$ . A luminosity of  $10^{29}$  would give Rubbia about 10 Ws and

1-2 Z° a day, he estimates, allowing for his detector efficiency.

CERN machine physicists have however not yet attempted to "tune" the collider to give its maximum luminosity. Two effectively independent factors of 50 could be obtained relatively easily, it is believed, which would bring the machine within a factor of 2 of a luminosity of 10<sup>29</sup>. The remaining factor of 2 might be made up within a year, machine physicists feel, with 10<sup>30</sup> remaining so far a very distant goal.

More easy to check are the cosmic ray results. These indicate that some extraordinary and inexplicable interactions may set in at centre of mass energies of the order of 1,000 GeV (This is around twice the collider energy, but the cosmic ray experiments have a detector threshold at about that level. Rushbrooke believes, so the physical threshold may be lower.) These Centauro events - of which only five or so have been observed, cosmic ray intensities being so low at this energy - show the production of very large numbers of charged particles (track multiplicity) and a mysterious near absence of neutral pions. Also the average transverse momentum of these and other high energy cosmic ray events rises with multiplicity, something quite unknown in lower energy data.

However, so far neither UA1 or UA5 have found any clear indication of these phenomena at the collider — though exact results await more precise data analysis. Confirmation of the cosmic ray results may have to wait for higher statistics — or for a collider of even higher energy, such as the 2,000 GeV centre of the mass energy collider being planned at Fermilab near Chicago for action in 1984 or 1985 (Ronald Reagan willing).

Robert Walgate is Chief European Correspondent of Nature.

One of the first 540 GeV p-p events to be recorded in the Cambridge-Bonn-Brussels-Stockholm streamer chamber (experiment UA5), showing clear forward and backward cones of tracks. The streamer chamber is the only detector on the collider to record particle tracks clearly close to the interaction point. It will provide a first survey of the physics of interactions at these new energies.

Latters, C.M.G., Fujimoto, Y., & Hasegawa, S. Physics Reports 65, 3 (1980).

# How cells live together

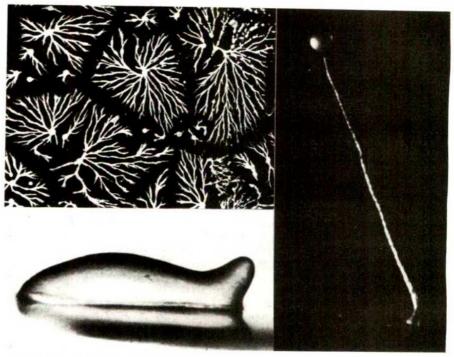

from Robert Kay

THE cells of a higher organism normally behave in a completely social way; it is the occasional deviant - such as a cancer cell - that attracts our attention. But how is cooperation between cells in a multicellular organism established? The problem is clearly seen in the cellular slime moulds, such as Dictyostelium discoideum. They feed as free-living amoebae, but when starved the cells aggregate by chemotaxis (to cyclic AMP) forming a small multicellular organism. This 'slug' though without the benefit of nerves or sense organs, can orientate and move towards light or heat. Eventually it differentiates into a fruit, with a stalk supporting a mass of spores. It was apparent from a recent meeting\* that to establish multicellularity cell-to-cell adhesion (and production of a sheath around the organism) and communication systems to control both movement and differentiation are necessary.

Cohesion is thought to be brought about by any of four systems in Dictyostelium: through contact sites A and B (cs A,B), by the discoidin lectins and by a 95K membrane protein from slug cells1. Appropriate antibodies and treatments can block cohesion via each system and now the pressing problem is to establish their respective roles in vivo. Progress is being made using cohesion-defective mutants. In a ts mutant described by Sussman (University of Pittsburg) cohesion during aggregation is normal at the restrictive temperature but is lost abruptly at the time slugs would form in the wild type. This indicates that the aggregative cohesion systems are replaced by a new mechanism in the slug. As the 95K protein does not appear at the restrictive temperature, it probably is part of the new mechanism; analysis of wild-type membrane extracts that restore cellular cohesion to mutant cells should test this supposition. Mutants affecting cs B, on the other hand, develop quite normally showing that cs B has only a minor role in developmental cohesion (Vogel, Max-Planck-Institut, Munich); its major function is probably in binding bacteria preparatory to phagocytosis and in cell-to-substratum adhesion. Similarly, in a related slime mould species cohesion is unaffected by mutation of its lectin (Francis, University of Delaware), so that by elimination, cs A is probably responsible for aggregative cohesion.

The signal coordinating forward movement of cells in a slug may or may not

Robert Kay is a member of the scientific staff of the Imperial Cancer Research Fund, Mill Hill Laboratories, London, UK.

After a few hours of starvation *Dictyostelium* amoebae initiate and relay cyclic AMP signals which guide them into streams leading to collecting points, where the cells mound up (top left, in dark field). These mounds transform into migrating slugs, each up to about 2mm long (lower left). The slug has an anterior organising 'tip' and eventually it differentiates into a fruit consisting of a mass of refractile spores supported by a cellular stalk (right).

be cyclic AMP, but the steering of the slug towards light involves something new. In a model proposed by K. Williams (Max-Plack-Institut, Munich) differential illumination of the slug tip generates a transverse gradient of an extracellular signal molecule, slug turning factor (STF), in the slug, to which cells respond by a change in direction, most likely by chemotaxis. The properties of STF are consistent with this model: it is made in response to light, high environmental levels disprientate phototaxing slugs and it is itself a slug chemotactic agent. Interestingly, STF, the stalk cell differentiation inducing factor DIF (Kay, ICRF, London) and an inducer of fruiting2 are all low molecular weight, hexanesoluble factors; whether these similarities point to identity or close relationship is as yet unknown.

Cyclic AMP signalling controls both cell movement and gene expression (for discoidin, at the level of transcription; J. Williams, ICRF, London) and it is becoming apparent that the coupling machinery used is similar to that of some mammalian hormones. Thus, Dictyostelium adenyl cyclase has a GTP binding and cholera-toxin-sensitive component analogous to the mammalian G protein (Leichtling and Rickenberg, National Jewish Hospital, Denver), whilst the major and most specific cytoplasmic cyclic AMP

binding protein (of about molecular weight 40,000; Veron, Pasteur Institute; Cooper, University of Michigan; van Driel, University of Amsterdam) inhibits the catalytic subunit of mammalian cyclic AMP-dependent protein kinase (Rickenberg) indicating that it too is part of a cyclic AMP-dependent kinase, as reported some years ago<sup>3</sup>. Similarly the Ca<sup>2+</sup>-mediated effects of cyclic AMP signalling on myosin phosphorylation involves calmodulin (Moruta, Max-Planck-Institut, Munich).

It has long been suspected that coordinately regulated genes (such as those regulated by cyclic AMP) might be distinguished by a common control element (see, for example, ref. 4). Just such an element may now have been found (Lodish, MIT). It is a sequence 300-500 bases long, interspersed in the genome and transcribed into 50 or more messenger RNA species by the fifth hour of development, but absent from vegetative RNA. Different sequences mark other groups of mRNAs present later in development and in growing cells5. By a fortunate coincidence a powerful means for finding the function of these sequences is now at hand. Firtel (La Jolla) described the first efficient transforming plasmid in Dictyostelium which has a selectable marker with a suitable Dictyostelium promoter and origin of DNA replication,

<sup>\*</sup>The conference on Gene Expression and Membrane Changes in Cellular Slime Molds was organized by Gunther Gerisch and held at Tutzing, September 2-6, 1981 with support from the European Molecular Biology Organization and the Max-Planck-Gesellschaft

and can give transformation frequencies as high as 1 in 104 cells. It should now be possible to see what happens to a foreign gene introduced into the cell attached to one of the above putative control sequences. In principle it should also be simple to isolate genes essential for development by complementing developmental mutants with wild-type DNA inserted into the plasmid.

The Dictyostellum slug is a sort of freeliving embryonic field and there is great interest in how a regulative pattern of prestalk and pre-spore cells is established in it. The problem divides into two: what induces an amoeba to differentiate into a pre-stalk or a pre-spore cell and then what establishes the spatial pattern of cell types? From work with isolated cells it appears that cyclic AMP is required for both stalk and spore differentiation but that DIF can, by favouring stalk formation, control the

Hermen, R.J. & Dievickoon, E. H. Schwicz 1803, 349 (1909) Kmmel, A.R. & Pittel, R.A. Cell 16, 787 (1979) Neture 291, 532 (1981) Le Rosth, D., Shilosch, J., Roth, J. & Lemsak, M.A. Proc. metr. Acad. Sci. U.S.A. 77, 6184 (1980)

choice of pathway (Kay). Several groups (Takeuchi, University of Kyoto; David, Munich University; Durston, University of Utrecht; MacWilliams, University of Massachusetts) strongly felt that sorting out of pre-stalk and pre-spore cells is an important way in which patterning is established (see ref. 6). However, we are a long way from knowing if this is the major or only way to generate pattern, especially as during regulation of pre-stalk isolates, and in D. mucoroides slug migration (where a stalk is continuously laid down), cells seem to differentiate according to their position (Gregg, University of Florida).

It is evident that even the lowly multicellularity of Dictyostelium is complicated enough for our present comfort. It would be nice to know that the tricks learnt by aggregating slime mould amoebae are still used (along with new ones) by higher and less tractable organisms. Of course, until both are understood this remains debatable, but recent evidence that many mammalian hormones7 and their response mechanisms are also present in simple eukaryotes suggests that tricks once learnt are not forgotten.

Unfortunately, in an amorphous specimen orientation is random and so unspecified, and even in a crystalline specimen the outgoing signal cannot be directed with any precision. However, the near-edge data involve rather slow and easily scattered electrons which will scatter between several atoms before eventually returning to the centre. Having travelled more widely than single-scattered electrons their phase contains information about the threedimensional disposition of the neighbours, but is much more difficult to interpret.

The limitation of information to radial structure, that is, to the radial distribution function, is a general property of weak scattering probes such as X-rays, neutrons or electron microscopes. It is particularly restrictive in systems where a knowledge of bond angles as well as bond lengths is important to an understanding of the structure.

Having proved the technique for well characterized materials the Daresbury scientists can be expected to tackle more exotic systems such as multi-component glasses or liquids, or biological molecules for which structural information is not available in advance.

The X-ray absorption experiments which have been first past the post in the race to publish are in fact only a part of the activities planned by university and industrial groups using Daresbury. In the first instance two beams of radiation are available. One provides for X-ray topography, and for X-ray interferometry, as well as for the absorption experiments referred to above. The other, providing radiation at longer wavelengths in the vacuum ultraviolet and soft X-ray range has two main experiments. The first VUV station to be operational measures the photoemission of electrons from surfaces and has the capability of resolving the direction as well as the energy of the escaping electrons. The second experiment measures the absorption cross sections of atoms adsorbed on surfaces and provides information in the surface context very similar to the structural information available for X-ray absorption experiments performed on both samples. Both these experiments will further our understanding of surface structure - important in catalysts, semiconductor technology and other areas of surface science.

In the near future more beam lines will become available, one providing for experiments in the area of atomic and molecular physics. Another will make available radiation in the infrared region for experiments on large organic molecules thus extending even further the range of wavelengths and types of application of the facility.

D.J. Thompson's team at Daresbury is currently completing the final stages of fine tuning of the SRS which now operates to specification with a regular schedule of users. Soon a major enhancement of the source will be made with the installation of

# Tripping the light fantastic

from John B. Pendry

THIS issue of Nature contains the first data taken on the new Synchrotron Radiation Source (SRS) housed at the Daresbury Laboratory. The source is a 2 GeV electron storage ring, with a design current of 370 mA, dedicated to the production of synchrotron radiation. Scientists at British universities and laboratories now have access to their own central facility for synchrotron radiation which will enable them to compete on equal terms with scientists in other countries.

The paper, by Greaves, Durham, Diakin and Quinn, (see p. 139) is an extension of the now familiar technique of using X-ray absorption fine structure to determine local crystallography [Sayer et al. Phys. Rev. Lett. 27, 1204, 1971]. The principle is that X-rays eject an electron from the inner core of an atom. The X-rays can be tuned to a particular type of atom because the inner shell ionization energies are strong functions of atomic number. When the ejected electron encounters the atomic neighbours of the excited atom it can be scattered and some of these secondary waves get back to the central atom. There, because the electron is described by a wave function, an interference process takes

place that may suppress or enhance the absorption cross section according to the phase of the scattered wave. Increasing the X-ray energy changes the electron wavelength and modulates the phase in a way that depends on the distance of the scatterers from the central atom. In this way X-ray physicists have discovered how to make a microscopic radar station. So far we are on well-trodden ground. What is new about the Daresbury paper? The experiments reported are X-ray absorption measurements on copper and manganese and the message is not so much an unravelling of the spectra of these materials as a jeu d'esprit of experimental and theoretical excellence demostrating that these spectra can be easily and accurately measured and, what is more, interpreted in a region of the spectrum, the near-edge region, which has previously been regarded as too complex to provide useful information.

The ability to interpret near-edge data goes some way towards removing a restrictive aspect of the X-ray absorption technique. For a radar station to give complete information about surrounding objects the precise orientation of the aerial must be known when the signal is sent out. Otherwise what emerges is merely a radial map with no directional information.

John B. Pendry is in the Blackett Laboratory, Imperial College, London.

a powerful superconducting magent (called a "wiggler" for technical reasons) which will accelerate the electrons in the source so strongly that the spectrum of radiation, currently cutting off at a wavelength around 0.3 Å, will extend down to 0.1 Å.

Although synchrotron radiation sources will soon be widely available in numerous countries, the technique still shows massive potential for further development. The Daresbury ring at full power produces several tens of kilowatts of raw radiation, enough to destroy most experimental specimens. Yet, because the requirement is mainly for spectrally pure radiation, most

of the power is dissipated as heat in a monochromator. If by some means the power available could be channelled into radiation of one wavelength a new and even more extraordinary generation of experiments would become possible, investigating nonlinear properties of matter. Perhaps the most radical proposal is to combine the power of synchrotron radiation with the coherence properties of a laser and produce the so-called free-electron-laser. It is gratifying to see UK scientists involved in all phases of the development and exploitation of synchrotron radiation.

# **Coding complications**

from a Correspondent

READERS will recollect that the celebrated wobble hypothesis of Crick defines the nature of the interaction between the codons of messenger RNA and the corresponding anticodons of tRNA. In short, the codons are read one at a time by tRNA molecules. These form three base pairs between the bases in their anticodon and those in the codon that it responds to. The first two base pairs formed by the codon are standard Watson-Crick A-U or G-C pairs but in the third position G-U pairs are allowed, as are A-I, G-I and U-I where the I residue is in the anticodon.

Although there is considerable evidence that this is the normal mode of codon-anticodon interaction in both eukarvotic and prokaryotic organisms, evidence has been accumulating that things are not always as simple as this. Thus in mitochondria, it would appear that a single base in the third position of the anticodon can 'read' each of the four bases which might occur in the third position of a codon, or to put the matter another way, only the first two bases of the codon are relevant. This state of affairs resembles the 'two out of three' mechanism proposed by Lagerkvist<sup>1</sup>. More evidence for such anomalies now appear in two papers in Nature and in two in Cell.

Munz et al. (see this issue of Nature, p. 187) have studied serine specific tRNA in Schizosaccharomyces pombe. This organism utilizes two isoaccepting tRNASer with anticodons IGA and U\*GA (U\*is a modified uridine) respectively. The one with IGA should be able to respond to the codons UCU, UCC and UCA and the other only to UCA. By means of some clever genetic manipulations Munz et al. were able to show, in essence, that mutants in which the U\*GA species is not synthesized are not viable. If the possibility that the missing tRNA had some other essential role to play is excluded, this would seem to imply that UCA codons were not being properly recognized. The anomaly appears when it is noted that the other serine specific isoacceptor with IGA for its anticodon should have been able to recognize this codon according to the rules of wobble. Apparently it does not. The significance of this *in vivo* result is increased when it is realized that the bulk of the evidence for A-I interactions is derived from *in vitro* experiments.

Meanwhile, Diamond, Dudock and Hatfield<sup>2</sup> have isolated and sequenced an unusual tRNA species from bovine liver. This accepts serine but has CmCA for its anticodon, an anticodon normally expected to recognize the tryptophan codon UGG. The anomaly appeared when it was found from in vitro binding experiments that the tRNA responded to UGA (which is normally the opal stop signal) but not to UGG or any of the serine codons. It was further shown that the tRNA could act as a suppressor of termination as the first result might suggest. In other words the Cm in the third position had 'read' A rather than G as demanded by the wobble hypothesis. This result for a eukaryote had been anticipated in the work of Hirsch3 who described a tRNATrp in E. coli which had an anticodon CCA but which responded to UGA codons. Both the eukaryotic and the prokaryotic tRNA molecules also had anomalous features in their sequences in the vicinity of their DiHU stems and the possibility remains that this feature is somehow related to their anomalous codon reading properties.

Another curious anomaly has been discussed by Bienz and Kubli (see this issue of *Nature* p 188). *Drosophila melanogaster* 

produces two major tRNATyr species one of which has the first position of its anticodon occupied by the modified Q base. The one with the unmodified anticodon, GUA, but not the other, is capable of acting as a suppressor to the amber termination codon UAG; in other words it can recognize UAG and insert tyrosine so preventing termination of translation. Again we have a wobble anomaly in that the interaction in the third position is between two G residues. The discovery of this naturally occurring suppressor in Drosophila was aided by an interesting assay system for breakthrough or suppression of a chain termination signal. This involved injecting into a Xenopus oocyte some of the tRNA to be assayed and some TMV RNA. If suppression occurred, this resulted in the formation of a 160,000 molecular weight protein, identifiable by polyacrylamide gel electrophoresis. Thus Bienz and Kubli also showed that wild type tRNATyr from yeast (with no Q base) would also act as suppressor in this system. They suppose that the presence of the Q base somehow inhibits the misreading of the UAG codons involved in this type of suppression.

Finally Bossi and Roth4 report on a different sort of suppressor effective in the suppression of the effect of a frameshift mutation. A frameshift mutant occurs when an extra base pair is inserted or a normal one left out during the process of replication. In either case the reading of the bases constituting the codons gets out of phase when the site of the mutation is encountered during translation. This results thereafter in a garbled polypeptide. Such a garbling of the message due to an insertion could be corrected if a tRNA was available which read four bases instead of three at a site near to the original mutation. Several mutant tRNA species can be produced which have this effect. Most of them respond to a region of the messenger RNA where there is a sequence of four identical bases; reading of the fourth base, so to speak, takes up the extra inserted base. The mechanism by which this occurs is obscure; maybe four base pairs are involved or maybe there is some sort of ambiguity as to which of the two possible triplets in the run of four the tRNA responds to. Bossi and Roth however, now describe a new suppressor, SufJ, which responds to sequences of four bases: ACCU, ACCC and ACCA (the sequence ACCG has not been tested). In other words it recognizes the triplet ACC but pulls the fourth base through the reading frame. This seems to be a sort of three out of four reading mechanism reminiscent of Lagerkvist's idea.

Simple explanation to account for these puzzling phenomena are not in sight but one thing seems certain: our once clear picture of the mechanism underlying the translation of the genetic message is developing a plethora of unbecoming flaws.

# Eight new Nobel laureates

# A spectrum of achievements

from David D. Burgess

One half of the Nobel Prize in Physics was awarded jointly to Nicolaas Bloembergen, Harvard University and Arthur L. Schawlow, Stanford University, for their contribution to the development of laser spectroscopy, and the other half to Professor Kai M. Siegbahn, Uppsala University for his contribution to the development of high-resolution electron spectroscopy.

SPECTROSCOPY, the study of all aspects of the interaction of electromagnetic radiation with matter in all its forms, not necessarily simply atomic or molecular, (undergraduate memories of thousands of atomic energy levels notwithstanding!), remains by its very nature one of the most powerful tools in large areas at the frontiers of both physics and chemistry. What is more interesting is that the prize has been given to this year's three Nobel laureates not for a specific scientific application, but for a more general and extended series of developments in technique. For obvious physical reasons the first demonstrations of methods of the type pioneered by the three Nobel winners have been in relatively 'pure' areas of atomic and molecular physics. However, the likely impact is much wider both scientifically and with important uses already developed in some technological and industrial spheres.

Schawlow and Bloembergen share half the prize for developments in laser spectroscopy. Some spectroscopic applications of lasers, of course, are simply extensions in kind of conventional techniques. Obvious increases in spectral resolution (from the very narrow bandwidths available), in signal (from high input intensities) or in time-resolution (from short pulse length) have been widely exploited. However, what Schawlow himself termed "The Laser Revolution in Spectroscopy" goes much deeper, stemming from two separate features which, in the visible and UV, occur only when laser sources are used. One is the ability to reach intensities at which the interaction of an atom or molecule with the electromagnetic field dominates that of all other interactions with its environment. whether radiative or collisional. The second is that the interaction of the atom or molecule with the electromagnetic field itself may become nonlinear.

Schawlow's achievements primarily relate to the first point. The power of spectroscopy becomes greatly enhanced if specific atoms or molecules in an ensemble can be 'tagged' in order to distinguish them from their surroundings, for example, by

selectively exciting only specific chemical or isotopic species, specific velocity subgroups, specific bound states, and so on. Almost the only way to do this is by interaction with laser radiation. A trivial calculation shows that at optical frequencies, thermal light sources, however bright and well-focused, cannot in general provide irradiances sufficient to cause significant selective excitation in the face of the always competing spontaneous radiative decay of the selected atomic or molecular state. Other excitation methods, for example, with pulsed electron beams, are not usually state selective. However, laser radiation provides both the intensity and the spectral resolution to change any selected state population in a sample at will, almost regardless of competing processes, and therefore to 'tag' chosen atoms.

When widely tunable lasers first became available in the late 1960s, Schawlow (a progenitor of the laser itself in his earlier work with Townes) left the then fashionable topic of laser development largely to others and with his group concentrated on a series of spectroscopic applications, often of a devastating simplicity and elegance. Prime amongst these was the development of 'Dopplerspectroscopy, by saturation spectroscopy, by 2-photon excitation, and by polarization spectroscopy, in which limitations on resolution always set previously by the thermal motions of atoms and molecules in a sample were removed either by selective excitation of particular velocity sub-groups, or in 2-photon spectroscopy by the actual cancellation of the Doppler shift regardless of the individual absorber's velocity.

The impact of the consequent vastlyincreased resolution on atomic and molecular physics is obvious, with a remeasurement of the Rydberg to increased precision by the Stanford group, a greatly increased ease of observing, for example, isotope shifts or high quantum states now exploited by many groups worldwide, and proposals even for looking at aspects of atomic physics related to current Unified Field Theories. Schawlow and his collaborators also demonstrated other possibilities of the immense sensitivity of laser spectroscopy, for example the capability of detecting just one atom of a given species against a background of other

species of almost arbitrary density, at one step not only pushing back the boundaries of chemical trace analysis by several orders of magnitude but indeed extending them to their ultimate physical limit. More recently, Schawlow has developed spectroscopic methods simplifying the analysis of molecular structure by selectively laser-tagging specific states.

Many of these spectroscopic developments have applications far outside pure atomic and molecular physics. The most obvious case is Doppler-free spectroscopy which is very intimately related with some schemes for obtaining efficient laser separation of fissile isotopes. However, many of the applications of the vast increase in spectroscopic sensitivity remain to be explored. (A single but rather nice example, given in a review by Letokhov at the recent Heidelberg European Atomic Physics meeting, is that the enormous sensitivity of laser spectroscopy for measuring relative isotopic abundance may now render all other radiocarbon and related dating methods quite obsolete.)

Bloembergen's work includes both theory and experiment in areas very similar to those described above, but perhaps best known is his contribution to the analysis of the possible nonlinear interactions of an atom or molecule with the electromagnetic field itself when the field intensity is high. The number of such nonlinear processes is vast. As well as fundamental interest many already have technological applications, whether to parametric losses in optical communication systems, spectroscopic analysis of jet engine exhausts via CARS (coherent anti-Stokes Raman Spectroscopy), atmospheric self-focusing of high-intensity laser beams due to nonlinear refractive indices, or recent developments of 'phase-conjugate' reflectors opening the possibility of optical systems in which aberrations and defects, however severe, are automatically self-cancelling. Important spectroscopic applications result from the availability of frequency up- or down-converted coherent sources in difficult spectral regions such as the vacuum ultraviolet and also from the more direct use of related '4-wave mixing' processes such as CARS and its derivatives as immensely sensitive spectroscopic tools.

The theoretical prescription provided by Bloembergen and his group, notably in a crucial paper in 1962, provided a suitable framework for distinguishing between and analysing the many possible competing nonlinear effects, particularly processes leading to frequency up or down

David D. Burgess is Professor of Spectroscopy at The Blackett Laboratory, Imperial College of Science and Technology, London. conversion, laying an immensely timely foundation for the type of applications already mentioned. Lately, Bloembergen has also become interested in a further technological possibility of selective laser spectroscopy of molecules, that of laser-induced chemistry, or laser catalysis, in which the direction and speed of a chemical reaction may be controlled by selective excitation of specific states in the reactants, or by selective destruction of the reactant products.

Laser spectroscopy has taken a large share of the fashionable limelight in recent years, but the award of half of the prize to Professor Kai Siegbhan is a reminder of equal recent progress in areas where lasers are not yet available, particularly the VUV and X-ray regions. Siegbahn's achievements relate to specific uses of photoelectron spectroscopy, the accurate measurement of the energies of electrons ejected by atoms or molecules irradiated with VUV or X-ray wavelengths. Siegbhan's contribution has been ESCA. Electron Spectroscopy for Chemical Analysis. In the complex spectra of most molecules, the structure of the individual atomic valence states is so perturbed by the bonding process that even in simple cases the visible or ultraviolet spectrum is not usually an a priori guide to the atomic constituents. Siegbahn realized that this could be overcome at X-ray wavelengths. the inner atomic electrons being largely shielded from the molecular environment, and the excitation energies therefore remaining characteristic of the atomic species involved. However, with laser techniques yet unavailable at X-ray wavelengths, orthodox emission or absorption spectroscopy does not provide a full basis for such an analytic method, emission requiring temperatures frequently sufficient to destroy the molecule of interest, and absorption work often needing excessively large samples. Siegbahn, therefore, used the alternative technique of energy analysing electrons ejected from the inner shells of atoms in molecules irradiated with specific X-ray wavelengths, a technique applicable to relatively small samples. The spectra so obtained additionally allow the investigation of the particular bonding environment of each atomic species, as small 'chemical shift' of the inner-shell binding energies by outer bonding electrons remains sufficient for aspects of the bond to be characterized without loss of the atomic identity of the spectra needed for direct chemical analysis.

In the past fifteen years spectroscopy has ceased to be simply a powerful but established technique, in some ways changing technically more than at any time since Newton. A huge challenge remains in both pure and applied science in the yet untapped applications of the type of techniques developed by the three Nobel winners in what now almost constitutes a completely new subject.

# Hemispheric modes of consciousness in the human brain

from Colwyn Trevarthen

One half of the Nobel Prize in Physiology or Medicine was awarded to Roger W. Sperry, California Institute of Technology, for his discoveries concerning the functional specialization of the cerebral hemispheres.

ROGER SPERRY, a leader among students of the functional design of the brain for forty years, might well have received the Nobel Prize for experiments he did in the 40's on the self-sorting of nerve pathways regrowing after surgical rearrangements in fish and amphibia. Many neurobiologists still see that as his greatest work.

The split-brain studies for which he received the prize last month led to discoveries about the human brain which are, however, of far greater importance for psychology. They showed that each human cerebral hemisphere, when disconnected from the other by surgery, could formulate consciousness, feelings and intentions on its own and that left and right sides had different mental abilities.

The experiments with human subjects came directly out of micro-surgical research at the University of Chicago on the transfer of learning from one side of the brain to the other in fish. When Sperry and Ronald Myers applied this approach to cats in the 1950's, they achieved the first convincing surgical duplication of the brain systems serving memory formation and awareness in one animal. Their brilliant, microscopically controlled operations sliced through the cross-over of visual input pathways under the brain, and the corpus callosum between the cerebral hemispheres.

Sperry's studies of split-brain cats and monkeys continued at the Californian Institute of Technology after he became Hixon Professor of Psychobiology there in 1954.

Then, in the 1960's, the elegant behavioural tests he had already devised for animals showed Sperry the way to effective study of human commissurotomy patients. This gave the breakthrough to clearer understanding of specifically human states of mind.

A Los Angeles neurosurgeon, Joseph Bogen, observing the rapid recovery of monkeys after Sperry's split-brain surgery, recalled that the corpus callosum of a human being could be transected safely in selected patients with uncontrollable epilepsy, to interrupt the seizures that were devstating these peoples' lives. A small

Colwyn Trevarthen is Reader in Psychology in the Department of Psychology, of the University of Edinburgh.

group of patients were operated upon by Philip Vogel and Bogen during the 60's producing, a successful alleviation of their epilepsy and a marked improvement in their health. Sperry worked with Bogen and a number of graduate students, of whom Michael Gazzaniga was the first, in the discovery of a most extraordinary division of human consciousness in these persons: a duplicate state of mind largely hidden when the patients were in free mastery of their experience and actions. Sperry led a systematic exploration of the full scope of this effect and so clarified a uniquely human division of mental tasks between the left and right halves of the

That parts of the left hemisphere are dominant in the control of speaking and writing and for understanding language was discovered in the last century. Observation of the psychological effects of wounds in different parts of the cortex produced evidence for each and all of the hemisphere differences that Sperry disclosed in his investigation of commissurotomy patients. But the history of this quest did not allow a coherent overview. There had never been a brain chart like Sperry's which summarized the basic division of functions, giving equal attention to both hemispheres. Even though a group of psychologists had been saying since the 40's that the right hemisphere could be superior to the left in certain non-verbal visuo-spatial kinds of detection and reasoning, their point was not well-taken by the majority of neurologists who were inclined to identify human intelligence with verbal intelligence.

The tests devised by Sperry's group showed that an isolated left hemisphere had clear superiority for functions linking a sequential pattern of logic with the production of speech and writing. They also showed that right hemisphere consciousness was not a weak copy of the left. It could perform some tasks better than the left even though it could not use elaborate verbal imagery or rational thinking of the propositional variety. Thus, the tests clarified our intuitive nonverbal insight and concrete awareness and drew attention to the work the brain must

Accounts by R.W. Sperry of his work are found in Cerebral Organization and Behaviour, Science 133, 1749 (1961); Mental unity following surgical disconnection of the cerebral hemispheres, Harvey Lectures 62, 293 (1967); Mind-Brain Interaction: Mentalism, Yes: Dualism, No. Neuroscience 5, 195 (1980); Changing Priorities, Annual Review of Neuroscience 4, 1 (1981).

do to directly percive and understand persons and things in the humanly ordered world about us. The right hemisphere was shown, for example, to be strongly preferred for feeling strange shapes in the hand, for copying drawings and for recognizing faces.

Sperry and his students, notably Jerry Levy, Robert Nebes, Harold Gordon, Eran and Dahlia Zaidel and the writer, adapted psychological tests to show how a splitbrain person could be conscious with one halfof the cerebral cortex at a time, or how he or she might choose to distribute a given cognitive task between the two disconnected halves. In all this work, which has produced many renowned scientific papers, Sperry acted as navigator and critic, employing his remarkable literary skills to draw the pieces of the puzzle into a bold harmony of primary principles.

Sperry has written important papers on the philosophical implications of splitbrain research, regarding the casual potency of consciousness as a spatiotemporal brain process that creates reality, goals, values, knowledge and skills in brain organs with a definite inherited anatomical design. Cerebral anatomists are now actively seeking inborn differences in the organization of cortical tissue in the two hemispheres. Psychology is encouraged to look inside the mind to understand internal and preordained standards of 'will', 'desire', 'imagination' and 'understanding' that condition how experience will affect our actions.

The studies of split-brain patients have opened the way, also, to a developmental approach or to an embryology of the mind. Human cognitive systems grow over many decades. Interaction of the hemispheres while they develop in the fetus and through childhood results in a segregation of major functional systems in a partnership or federation. Power sharing is thereby achieved with a much higher efficiency in the integration of an individual's purposes and adaptive actions. This process takes a different course in right and left handers, in males and females, educated and uneducated, the blind and the deaf. There takes place in each of us a progressive division of brain work and generation of a unique bihemisphere condition. Genetically based hemispheric specialisations enter into regulation of the individual's place in his family, his society, his culture and in the history of his community.

been known that the contralateral eye sends fibres to laminae 1, 4 and 6 in the nucleus which relays information to the visual cortex, with laminae 2,3 and 5 supplied by the ipsilateral eye. Hubel and Wiesel made electrolytic lessions limited to a single lamina in the relay nucleus and found degenerating nerve endings in a series of regularly spaced bands about  $400 \mu$  wide and separated by  $400 \mu$  throughout the visual cortex. If their lesion in the relay nucleus encroached on an adjacent lamina, the cortical degeneration became continuous.

The existence of right and left eye ocular dominance columns was fully confirmed by other methods, and they have been found in cats, galago and the macaque, but not in the mouse, the tree shrew or the squirrel monkey. The basic unit seems to be an about one millimetre square 'hypercolumn', containing left and right ocular dominance columns crossed approximately at right angles by about ten orientation columns.

It was previously known that retinal fibres project on the visual cortex in an orderly fashion, so that in man the fovea, the point of most distinct vision, is represented at the occipital pole and the extreme periphery at the front end of the calcarine fissure, and it was known from Gordon Holmes's work that the fovea had a disproportionately large area of representation in the cortex. It became clear that a hypercolumn of one square millimetre in the foveal area would deal with a solid angle of 10 minutes of arc, whereas a similar hypercolumn in the far periphery would cover about 10 degrees. There is a continuous representation of the visual field along layer IV in each ocular dominance column, half overlapped by the representation in the adjacent column for the other eye. In this way topographical representation, provenance from each eye and orientation are all represented in a two dimensional sheet of cortex.

Hubel and Wiesel have also established that ocular dominance and orientation preference is present at birth in cats and monkeys without visual experience. Newborn animals differ from adults in having a less sharp tuning of orientation preferences and less binocular interaction. These differences seem to be due to lack of visual experience rather than immaturity as animals whose eyes are kept closed for some weeks from birth show little improvement on the state at birth. The system is still plastic, however, since closure of one eye soon after birth results in the take-over of most of the cells of layer IV by afferent fibres from the open eye so that after some weeks the deprived eye drives very few cells in the cortex. This plasticity lasts for about three months in kittens, somewhat longer in monkeys and up to one to two years in man. Closure of one eye after this 'critical period' has no permanent effect and reopening and retraining must take place during the critical period if there

### Visual machinery of the brain

from David Whitteridge

One half of the Nobel Prize in Physiology and Medicine was awarded jointly to David H. Hubel and Torsten N. Wiesel, both of the Harvard Medical School, for their discoveries concerning information processing in the visual system.

THE work of Hubel and Wiesel over the last twenty years has established two main points: first, that the visual cortex has a remarkably ordered fine structure, composed, in the monkey, of about a thousand units of identical structure, each of which contains mechanisms for the analysis of all the data from corresponding parts of the visual fields and, second, that these orderly units are very largely established by genetic mechanisms during prenatal development and can be modified by visual experience only during the first few months of life.

Their first major discovery was that cortical visual cells are excited by bars, light or dark, or by single edges, and that each cell responds optimally to a particular orientation of the stimulus. This was previously unsuspected, as ganglion cells of the retina and the cells of the lateral

geniculate (relay) nucleus were known to have round fields, usually concentrically arranged so that an excitatory centre would be surrounded by an inhibitory surround and vice versa.

To analyse all possible patterns it would be necessary to have sets of cells sensitive to a complete range of orientations. In the cortex such an organization has been found. Cells of one orientation occupy a "column" about 50 wide, extending from the surface to the white matter, with columns of approximately ten degrees different orientation, displaced clockwise or anticlockwise, on each side. A horizontal penetration through the cortex encounters a regular series of such orientation columns occasionally interupted by reversals. Much later, Hubel and Wiesel were able to display the full extent of orientation columns by injecting radioactive deoxyglucose, and exposing the animal to light bars at a single orientation. A series of regularly spaced thin curved columns were found to be stained.

They established a second independent set of 'ocular dominance' columns each of which received fibres from one eye only and contained cells which were driven exclusively (in cortical layer IV) or predominantly by that eye. It had long

David Whitteridge is Emeritus Professor of Physiology in the University of Oxford. is to be any recovery. The mechanism by which active fibres can apparently displace inactive fibres is obviously of great importance and as yet not understood.

This knowledge of the organisation of

the primary visual cortex is being used to understand the activities of other visual areas and is forcing reconsideration of present ideas on the *modus operandi* of all other cortical areas.

### Rules for chemical reactions

from Graham Richards

One half of the Nobel Prize in Chemistry was awarded to *Kenichi Fukui*, Kyoto University and the other half to *Roald Hoffmann*, Cornell University, for their theories concerning the course of chemical reactions.

THEORETICAL CHEMISTS often seem to work at one of two extreme ends of the same problem. Either they do highly accurate calculations on small molecules or crude, even qualitative, investigations of larger molecules which are closer to the molecules synthesized and used at the laboratory bench. Both Fukui and Hoffmann belong to the latter school. Their work has added an excitement to broad areas of organic chemistry. The culmination of their research in the form of Woodward-Hoffmann rules represents what is perhaps the most significant single step in organic chemistry in the post-war period.

The chemistry of a molecule is determined by the distribution of its electrons and by how tightly these electrons are held at particular locations in the molecule. Fukui's method of frontier molecular orbitals concentrates on the electrons which are the most loosely bound. If a reactant is involved in donating electrons to form bonds then the electrons

Graham Richards is lecturer in Physical Chemistry at Oxford University.

involved are most likely to be those most easily removed. Conversely, if a molecule reacts by virtue of acceptance of electrons into a previously unoccupied molecular orbital then the bond will be created in the region where the extra charge is most readily accepted. Frontier molecular orbital theory then looks quantitatively at electron density distributions in the occupied molecular orbital which is highest in energy terms and at the lowest unoccupied molecular orbital. The new acronyms HOMO and LUMO abound in current literature on organic and medicinal chemistry.

Frontier orbital theory is based on the perturbation treatment of molecular orbital theory introduced by Coulson and Longuet-Higgins. It deduces conclusions about chemical reactions by looking at the interaction of the reactants, assuming that the position of the transition state on the potential energy surface can be deduced from the initial slope along the reaction coordinate; the smallest slope is identified with the lowest energy transition state and consequently the fastest reaction or preponderance of products. Fukui's ideas were developed and exploited in the early days when theoreticians were not blessed with large computers and in consequence restricted to pi-electron systems and the simple Hückel molecular orbital method. This limitation nonetheless allows consideration of the reactivities of all the aromatic molecules of orgnic chemistry

since their reactions are largely those of the delocalised pi-electron system built from atomic 2p atomic orbitals.

Hoffmann's first major contribution to theoretical chemistry was to extend the formalism of the pi-electron Hückel theory to include sigma electrons. Thus molecules of the aliphatic type such as ethane could be considered as well as aromatics such as benzene. This simple semi-empirical molecular orbital technique is still widely used since it can treat very large molecular systems without demanding anti-social amounts of computer time.

Experience gained from extended Hückel calculations led to the now famous Woodward-Hoffmann rules which Fukui showed could be explained by frontier orbital theory, (although there are other explanations including symmetry arguments). The idea of Hoffmann and the late Nobel laureate R.B. Woodward explains why, for example, maleic anhydride reacts easily with butadiene but not at all easily with ethylene. In the former case two new carbon-carbon bonds are made simultaneously and the electrons which are involved complete a circuit. Concerted and cyclic reactions of this type are called pericyclic and this example is a cycloaddition. Woodward and Hoffmann's rules start with a consideration of the molecular orbitals of the reactants and match up the electron densities in occupied and unoccupied molecular orbitals. A correlation diagram permits a simple decision to be made as to whether a particular reaction is allowed or not.

Vast numbers of applications of the Woodward-Hoffmann rules are to be found in recent literature and perhaps the best testament to the power and range of applicability of these rules is to quote in its entirety the first paragraph of chapter 12 from the eponymous pair's book *Conservation of Orbital Symmetry*; Chapter 12, Violations "There are none!"

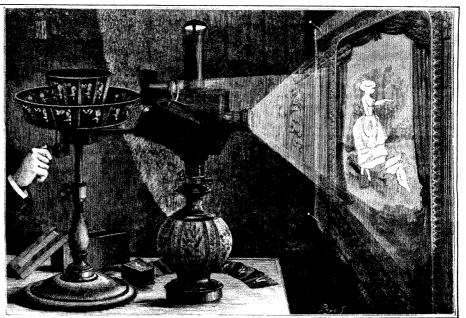

### 99 Years ago

THE PROJECTION PRAXINOSCOPE

M. Gaston Tissandier describes in La Nature an ingenious adaptation of the praxinoscope by means of which the images are projected on a screen, and are visible to a large assembly. M. Reynaud, the inventor obtains at once the projection of the scene or background - by the object-glass which is seen at the side of the - and of the subject, by another object-glass which is shown in front of and a little above the same lantern. In making the two parts of the apparatus converge slightly, the animated subject is brought into the middle of the background, where it then appears to gambol. A hand-lever on the foot of the instrument allows a moderate and regular rotation to be communicated.

### A new era in mammalian gene mapping: somatic cell genetics and recombinant DNA methodologies

F. H. Ruddle

Department of Biology, Yale University, PO Box 6666, New Haven, Connecticut 06511, USA

Mammalian gene mapping techniques are now sufficiently advanced to contribute significantly to prenatal diagnosis and to human molecular genetics. Restriction fragment mapping can be used to place polymorphic genetic markers at random sites within the genome, and these sites used to assign genes responsible for disease conditions to a chromosomal region. Somatic cell genetic techniques can then be applied to saturate that region with additional restriction fragment markers, some of which will be closely linked to the disease gene. Closely linked restriction fragment markers, especially flanking pairs of markers, can act as predictors for the transmission of defective genes to offspring. A series of tightly linked flanking restriction markers might in addition contribute to the eventual isolation and cloning of the disease gene itself.

SOMATIC cell genetics provides a means of analysing the complex genetic organization and regulation of higher eukaryotes<sup>1,2</sup>. Although it has contributed significantly to our knowledge of mutagenesis3, genetic complementation4 and gene regulation<sup>5</sup>, its major success has been in gene mapping, especially in man<sup>6,7</sup>. Two approaches to the analysis of the human genome have been remarkably successful. Recombinant DNA techniques have allowed several genes and their flanking DNA regions to be sequenced, and using such techniques, functional regions, such as promoters for RNA synthesis, have been identified and mutations and deletions precisely defined. At the level of the whole chromosome somatic cell genetic techniques have been used to map hundreds of human genes directly, and hundreds more have been mapped on the basis of known linkages to the first group. Until recently analysis of the intermediate level of human genetic analysis has been much less successful. Now, however, a variety of approaches make this range accessible as well. This review focuses on these approaches and on the way in which their concerted application will yield both a better understanding of eukaryotic genome structure, and information useful in clinical diagnosis.

### Gene transfer between mammalian cells

Gene mapping by somatic cell genetics depends primarily on parasexual events which facilitate the transfer of genetic material between cells (gene transfer) and the loss of transferred material from hybrid cells (segregation). In discussing gene transfer systems, it is convenient to distinguish between the donor cell which serves as the source of transferred genetic materials and the recipient cell into which donor genetic material is delivered. The resulting heterogenote is referred to simply as the hybrid cell. There are four ways of delivering genes into recipient cells:

(1) Cell hybridization: Fusion of two genetically distinct parental cells (for example, man×mouse) yields cell hybrids which contain initially complete parental chromosome sets. In such interspecific hybrids, one chromosome set is usually partially lost (segregation), and for convenience this set is termed the donor set. Hybridization thereby provides a means of transferring large numbers of donor chromosomes into a recipient cell. Hybrid clones can be established which retain a defined set of donor chromosomes.

- (2) Microcell-mediated gene transfer: Donor cells can be manipulated so that their chromosomes become isolated in microcells<sup>8</sup>, which may possess only one or a few donor chromosomes. Such cells can be hybridized to recipient cells, and thereby serve as convenient vectors for the transfer of one or a few intact donor chromosomes into recipient cells. An advantage of the microcell approach is experimental control over chromosome segregation.
- (3) Chromosome-mediated gene transfer: Cell-free preparations of donor chromosomes can be used to transform recipient cells<sup>9-10</sup>. In this system, whole chromosomes are taken up by endocytosis and then degraded into subchromosomal fragments. Fragments large enough to be detected by light microscopy as well as submicroscopic fragments have been described<sup>11</sup>. The lower limits of fragment size have not yet been
- (4) DNA-mediated gene transfer: Eukaryotic cells can be transformed genetically by purified DNA<sup>12</sup>. Two primary means of transfer exist: endocytotic uptake of calcium phosphate precipitated DNA, and direct injection of purified DNA into the nucleus by microcapillary pipettes. Transformation frequencies obtained by microinjection can be as high as 20% (ref. 13), whereas transformation by endocytosis of precipitated DNA (or the endocytotic uptake of chromosomes) is generally four to five orders of magnitude less efficient. In DNA-mediated transfer, the size of the donor fragment initially taken up by the recipient cell is invariably small, usually less than 50 kilobases (kb).

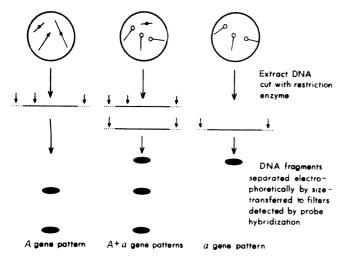

Thus it can be seen that through the choice of the particular gene transfer system used one can control within broad limits the amount and size of donor material transferred into a recipient cell. As we shall see below, this capability provides a means of regulating the resolution of gene mapping analysis.

### Gene mapping by somatic cell genetics

The assignment of genes to chromosomes and regions of chromosomes in somatic cell genetic systems is accomplished by correlating a particular donor gene or its product with a specific donor chromosome or a subchromosomal fragment <sup>14</sup>. More than 200 human genes have been assigned to particular chromosomal locations in the human genome by this method, bringing the total number of mapped genes in man to more than 400. On the average, four human genes are mapped per month

by the somatic cell approach, and as we shall see, this accession rate can be expected to increase dramatically in the next few years.

Until recently, the method of choice in gene assignment was the correlation of a particular gene product (such as an enzyme, structural protein or surface antigen) with an identifiable donor chromosome or fragment. This method has severe limitations, because it depends on the expression of the donor gene and thus precludes the mapping of genes which are expressed only in certain differentiated cells or of nucleotide sequences which have no coding functions. These drawbacks can be overcome by using nucleic acid hybridization techniques to detect donor genes directly. We first showed the feasibility of this approach in the assignment of the human  $\alpha$ - and  $\beta$ -globin loci using solution hybridization ( $C_0t$  analysis) of  $\alpha$ - and  $\beta$ -globin cDNAs with DNA preparations from hybrid clones containing different human chromosomes. These studies showed that the  $\alpha$ -globin complex mapped 15 to human chromosome 16, and the  $\beta$ -globin complex mapped<sup>16</sup> to human chromosome 11. The success of this method depends on the specificity of hybridization of the donor gene probe with the homologous donor human genomic sequence, and so appreciable cross-reaction with recipient cell DNA sequences will limit the use of solution hybridizaton as a gene mapping technique. This represents a serious restriction, because in many instances cross-hybridization of structural gene probes can be expected to occur, as we found to be the case when we attempted to extend the solution hybridization procedure to the assignment of the murine immunoglobulin genes. In this system, there was extensive cross-hybridization between cloned recombinant DNA probes of specific mouse immunoglobulin nucleotide sequences and the recipient (in this case, Chinese hamster) genomic sequences. This problem was solved by making use of donor and recipient differences in restriction endonuclease sites within or around the gene of interest and using the Southern blotting procedure to reveal these differences (Fig. 1). The differences in the location of restriction sites are diagnostic for the donor and recipient forms of a particular immunoglobulin gene. Using this approach, it was possible to assign the mouse  $\kappa$ ,  $\lambda$  and heavy chain complexes to chromosomes 617, 1618 and 1219 respectively. The restriction fragment mapping procedure has the advantage that it is independent of hybridization specificity, depending only on the restriction fragment length differences which occur frequently between species. This approach makes possible the mapping of any unique or low copy number nucleotide sequence, and within

Chromosome 1 correlates with the A gene pattern  $\therefore$  the A gene can be assigned to chromosome 1

Fig. 1 Restriction fragment mapping. The restriction pattern of the donor cell gene (A) differs from that of the recipient cell gene (a). The probable region of the genes is depicted by solid lines. Diagnostic fragments of different molecular weight are generated from the two genes by endonuclease digestion. The signature of the donor gene can be correlated with a particular donor chromosome.

a relatively short period, an impressive number of gene complexes have already been assigned in human and murine genomes using this procedure (Table 1). As the number of cloned DNA probes to specific genes is expanding rapidly, we can expect the mapping of such genes to increase commensurately.

Chromosome cloning techniques (that is, the isolation of single donor chromosomes in a host recipient cell) can also be used to assign a gene to small subregions on a particular chromosome and to establish the order of different genes along the length of the chromosome<sup>20</sup>. This can be accomplished by using donor cells which carry reciprocal translocations involving a particular chromosome. Such translocations occur at a relatively high frequency in human families where they are detected as a consequence of high abortion rates or congenital defects. A concerted effort has been made to collect cells from translocation carriers<sup>21</sup>; more than 300 such translocations have been stored, and for each the translocation breakpoints have been described in terms of chromosome banding patterns. If a gene has been assigned to a particular chromosome, then a series of translocations involving different sites along the chromosome can be used to delimit the position of the gene. This position has been termed the 'smallest region of overlap' (SRO)22. Translocations or deletions which arise spontaneously in the hybrid cells can also be used for this purpose. More than 100 human genes have been assigned to subchromosomal regions by these methods. Such regional mapping procedures lend themselves readily to restriction fragment mapping; for example, the human  $\beta$ -globin locus was assigned to the chromosomal subregion 11p125-p128 in this way

Human reciprocal translocations can also be used in conjunction with chromosome sorting techniques to fix the subchromosomal localization of genes. It has been shown that isolated mammalian mitotic chromosomes can be sorted into discrete size groups by fluorescence particle sorting<sup>24</sup>. Nearly every human chromosome can be resolved as a unique size class by this technique. DNA can be isolated from the sorted chromosomes and then hybridized with cloned probes in order to establish gene assignments. Translocations are particularly useful in this mapping procedure because they alter the size of a chromosome in a predictable way, causing a change in the sorting pattern, and thus enabling a suspected linkage relationship to be verified25. Drawbacks of the chromosome sorting approach involve the relatively long sorting times required for recovery of sufficiently large samples and the high cost of the procedure. Despite these limitations the technique can be expected to add another dimension to gene mapping methodologies.

Considering all the regional mapping procedures, probably the greatest potential lies with in situ hybridization26. This technique is used routinely to locate single copy genes in Drosophila polytene chromosomes, where they are amplified about 1,000 times. The older in situ hybridization procedures could reliably detect single copy genes amplified as little as 100-fold-but not less. Recently new procedures have been introduced which significantly increase the sensitivity and resolution of the method so that a single copy gene amplified 10-20-fold can be detected<sup>27</sup>. It may also be possible to detect unamplified unit genes using additional refinements; in fact, several investigators have claimed success in mapping single copy genes by *in situ* hybridization<sup>28-31</sup>. Recent innovations include: the use of <sup>125</sup>I-labelled nucleotide, introduced into DNA probes by nick translation, which produces radioactive probes of high specific activity (up to 10° d.p.m. per µg DNA)<sup>27</sup>; the use of dextran sulphate in the hybridization reaction mixture to increase hybridization efficiency<sup>32</sup>; single-stranded probes which do not hybridize to themselves, thus providing an additional increased efficiency of approximately five- to sevenfold<sup>33</sup>. More recently, it has been shown that biotin derivatives of cytidine can be produced (D. Ward, personal communication), which can be efficiently incorporated into probes by nick translation. DNA containing biotinized nucleotides can

be used as antigens to produce specific polyclonal or monoclonal antibiotin DNA antibodies. Such antibodies can be fluorescently, isotopically or enzymatically labelled, and then used as a second label against the polynucleotide probe. Labelled antibodies directed against the antibiotin DNA antibodies can also be produced and used to increase signal intensity.

Theoretically, combinations of the above techniques should permit the regional localization of unit genes. The in situ method is all the more promising when one considers that many gene loci exist as complexes containing clusters of related genes. If mixtures of the relevant probes were used, one would expect a corresponding increase in sensitivity. It may also be possible to use the in situ technique in combination with restriction fragment mapping of chromosomes using cell hybrids. For example, a cloned probe could be used initially to map a gene to a particular chromosome using the restriction fragment mapping technique, and then the same probe could be used in situ to localize the gene to a specific region on the chromosome. The advantage of the sequential procedure is that only one chromosome need be considered in the in situ analysis, thus reducing the possibility of error due to nonspecific binding of the probe to irrelevant chromosomes. Such an approach should improve the signal to noise ratio by 20-fold.

### Resolution power of mapping techniques

The resolution achievable by the subchromosomal mapping procedures described above lies in the range of 5–10 centimorgans. This estimate is based on the following considerations. Modern methods of chromosome banding permit the resolution of 850 bands per haploid genome<sup>34</sup>. Refinement of these methods can be expected to increase the band number to somewhat more than 1,000 (ref. 35). The total length of the human genome calculated in recombination units is about 3,000 centimorgans (ref. 36). Therefore, the number of bands is roughly one-third the number of centimorgans. Also relevant to the following discussion is the fact that the total human haploid nucleotide base pair number is about  $3 \times 10^9$ , and therefore there are an average of  $10^6$  base pairs (1 Mbp) per centimorgan.

Conventional low-resolution somatic cell genetic procedures can be expected to map genes to chromosomes and then within chromosomes to a resolution of 5–10 centimorgans. At the other end of the scale, high-resolution recombinant DNA procedures together with restriction site and nucleotide sequence analysis can be expected to provide mapping data from the level of the single nucleotide base pairs to the 100-kb level. These distances can be spanned by 'walking' along a chromosome from an identified cloned genomic DNA fragment using recombinant DNA techniques. This method involves isolating a DNA fragment within a genetically defined region by recombinant DNA

cloning from which the walk is started. This fragment is then used to probe a genomic library to identify clones which share a region of homology, but which extend beyond the initial fragment. These clones are then isolated, the process repeated and the linear nucleotide sequence extended. The 'walk' method combined with detailed cytogenetic maps has been used to advantage in *Drosophila*. However, *Drosophila* is especially well suited to this approach because there are relatively few redundant sequences which introduce false branch points in the walk, and because of the availability of the polytene in situ hybridization technique which provides a means of verifying progress along the chromosome (W. Bender, personal communication). However, mammalian genomes do not have these advantages.

Thus, in mammalian genetic linkage analysis a resolution 'gap' in the gene mapping techniques exists over the range 0.1-5.0 centimorgans (0.1-5.0 Mbp) (Fig. 2). This is a significant gap, because many functionally related clusters of genes, such as the human major histocompatibility locus, will fit into a space of this dimension. What mapping strategies might be devised to fill this gap?

Gene transfer systems provide possible approaches to intermediate level resolution analysis. All these methods depend on fragmenting linkage groups into small bits. In addition, all require a selectable marker in the linkage group of interest. The frequency of recovery of genes in linkage with the selectable marker provides information on the distance and order of genes with respect to the selectable marker. However, the requirement for a selectable marker has become less of a problem with the advent of DNA-mediated gene transfer. It is now possible to integrate various selectable markers into any linkage group by this procedure.

The three principal gene transfer systems suitable for intermediate level resolution analysis are: (1) DNA-mediated gene transfer, (2) donor chromosome breakage by irradiation and subsequent transfer to recipient cells by hybrid formation and (3) transfer of isolated metaphase chromosomes. The first system offers little advantage over walking, as the maximum fragment size is ~50 kb. The second method has already been successfully applied to linkage analysis by Goss and Harris37, who estimated the distance between the human genes thymidine kinase and galactose kinase to be 1.2 centimorgans by this technique<sup>38</sup>. The third method appears to have considerable potential for intermediate level resolution analysis, because a broad range of fragment sizes are generated by this procedure1 It has been shown that the procedure separates thymidine kinase and galactose kinase genes in 80% of transformants<sup>39</sup>, suggesting a potential for resolving genes separated by distances of 0.1 to possibly 0.05, centimorgans.

Klobutcher and Ruddle have recently introduced a breakagetranslocation based approach to middle-resolution gene

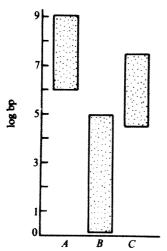

Fig. 2 Genetic mapping resolution by different methods. a, Gene mapping by somatic cell genetics; b, molecular genetic techniques; c, gene transfer and breakage-translocation methods. Ordinate = logarithm of base pair number.

mapping<sup>40</sup>. In this system, a donor chromosome is transferred into a recipient cell by one of the gene transfer techniques. The chromosome must carry a selectable marker which confers viability on the recipient cell when grown in selective conditions. An example would be the transfer of the thymidine kinase chromosome into a thymidine kinase-deficient recipient cell grown under hypoxanthine/aminopterin/thymidine selection. A second requirement is that the donor chromosome be lost (segregated) from the recipient cell at a frequency of  $\sim 3-10\%$  of cells per generation. A translocation between the donor chromosome and a recipient chromosome can give rise to an interspecific recombinant chromosome which is stably retained, and which carries the donor selectable gene and the recipient centromere (Fig. 3). Even though such translocation events are rare, the resulting hybrid cell possesses a 3-10% per generation growth rate advantage, and will rapidly come to constitute an appreciable fraction of the original population.

Independently arising recombinants of this type can be isolated and then the order and relative distances between genes in the chromosome segment lying between the selectable marker and the centromere can be analysed. In the first application of this approach, recombinants were obtained in which the human selectable marker thymidine kinase and the closely linked human constitutive marker galactonkinase were separated with a dissociation frequency of ~40% which indicates that resolution at the 0.1 centimorgan level can be achieved. The breaktranslocation system has several advantages: (1) a single well characterized cell line is used which continuously generates recombinant sports; (2) chromosome breaks are selected only within a well defined region determined by the donor centromere and the prototrophic, donor marker; (3) in primate/rodent combinations, appropriate chromosome staining techniques can be used which permit the detection of the chromosome break points and allow a cytological estimation of the size of the translocated donor fragment.

Thus, it can be seen that a variety of gene transfer procedures have potential for establishing the order of and distance between genes within the intermediate range of resolution. These techniques can be subjected to rigorous evaluation only when numerous unique nucleic acid probes have been isolated which map into appropriately short segments of mammalian genomes amenable to analysis.

## Cooperative interaction between mendelian and somatic cell genetics

In 1911 the first sex-linked gene (colour blindness) was mapped in man<sup>41</sup>. It was not until 1970 that the first human autosomal gene was mapped using a strictly mendelian approach. However, since 1970, around 50 additional autosomal genes

have been mapped in man using family analysis. This significant increase in the accession of autosomal genes controlling complex traits can be attributed in many cases to the previous chromosome assignment of genes by somatic cell genetics. The Rh gene, first identified in 1939<sup>42</sup>, is a good case in point. In 1971, its linkage to Pep C was recognized<sup>43</sup>, and when in 1972 Pep C was assigned to chromosome 1 by somatic cell genetics, the Rh gene was also assigned<sup>44</sup>. In many instances, the chromosome assignment of a mutant or polymorphic trait segregating in families has been facilitated by a linkage association with a second gene which had been assigned previously by somatic cell genetics. This is a promising development, as more than 1,000 unassigned human genes have been described and catalogued, many of which produce genetic disease<sup>44</sup>.

One can expect the assignment of complex organismal traits to chromosomes to be accelerated through the mapping of restriction fragments by somatic cell genetics. Restriction fragment mapping is accomplished by Southern blotting analysis, hybridizing labelled fragments to DNA preparations derived from interspecific somatic cell hybrids carrying one or a few donor chromosomes, assuming there are differences between the lengths of the homologous fragments of the donor and recipient species. Subsequently, linkage tests or in situ hybridization mapping would provide a regional assignment within a particular chromosome for a specific sequence. If several hundred restriction fragment markers selected randomly were mapped, they would be spaced at approximately 5-10 centimorgan intervals. It can be argued on theoretical grounds that such restriction fragment markers will be highly polymorphic within the human species 46. Wyman and White 47 have reported one restriction fragment length polymorphism in man which fits this description. DeMartinville et al. 58 have recently mapped this marker to human chromosome 14. Co-segregation within a family of a complex trait (a trait expressed only at the organismal level) and a specific restriction fragment polymorphism, previously assigned to a specific chromosome, would allow that trait to be mapped.

In practice, this approach to human gene mapping could be carried out in the following way. DNA samples can be collected from members of families segregating genes which control the expression of complex traits or disease conditions, analysed for restriction fragment polymorphisms, and the resulting polymorphisms tested for linkage with other co-segregating traits. In this way, a variety of genes amenable only to mendelian analysis can be assigned positions on the human gene map. Using this approach, it should by feasible eventually to map the chromosomal locations of all the major genetic disease genesfor example, Huntington's chorea, cystic fibrosis and xeroderma pigmentosum. One of the practical advantages of the restriction site polymorphism mapping technique is that a single methodological procedure can be used to study many genetic polymorphisms within a single kindred. In this manner, the restriction fragment length polymorphism method is similar to the standard practice of using serological tests for studying linkage relationships in human families.

Several techniques are available for the isolation of cloned DNA probes whose corresponding homologous sequences can be mapped. Some of these probes will represent sequences within genes of known function (for example, the globins or the insulins), while others will be of unknown function when first isolated. Fragments of both known and unknown function can be mapped and used as genetic markers equally well. To serve as discrete markers, the cloned fragments (probes) should be unique, single copy sequences. These can be obtained conveniently in cDNA libraries<sup>49</sup>. The cDNA probes have the additional advantage that they represent structural gene products and their biological function will ultimately become known. The cDNA probes will also be characterized to a degree by their tissues of origin. It is also possible to isolate DNA probes from genomic libraries, but in these instances the probability of recovering redundant sequences is significantly increased. Genomic sequences may, however, be subcloned,

subfragments tested for redundancy, and the desired unique sequences isolated.

Once a gene controlling a complex trait or genetic disease is mapped to a chromosomal region, additional restriction fragment markers can be mapped into that region using somatic cell genetics techniques. For example, Gusella et al.50 have produced cloned gene libraries from a man × mouse hybrid cell population carrying human chromosome 11 as a single donor chromosome. Such a library would contain fragments predominantly from the total mouse genome and a smaller set of clones containing DNA fragments from human chromosome 11. A subset of the human fragment clones will also contain repetitive human DNA species which can be detected by colony hybridization with labelled total human DNA. Gusella showed that in many instances the human repetitive sequences were contiguous with unique sequences. The single copy sequences could be isolated and then used as unique probes for the detection of their corresponding homologous sequences within chromosome 11. These were shown by direct analysis to map to chromosome 11 as expected. Subsequent regional mapping experiments assigned four such fragments to different regions of the chromosome. Thus, it is possible, using a cell hybrid which retains a defined donor genomic segment, to isolate cloned gene fragments which map specifically to that segment.

### Application of gene mapping to prenatal diagnosis

The ability to map restriction fragment markers randomly throughout the genome and to specific regions of chromosomes has obvious important implications for prenatal diagnosis, genetic screening of populations and paternity testing. Restriction fragment length polymorphisms closely linked to mutant alleles have already been used to predict genetic disease prenatally. In the case of sickle cell anaemia, Kan and Dozy have reported a polymorphism at a HpaI site 5,000 bp distant from the 3' end of the  $\alpha$ -globin gene<sup>51</sup>. When this site is present, a 7-kb fragment detectable with  $\alpha$ -globin probes is generated; when absent, a 13-kb fragment is produced. The HpaI site, which is responsible for the restriction fragment length polymorphism, is tightly linked to the  $\alpha$ -globin locus (5,000 bp is equivalent to 0.005 centimorgans) so that the probability of recombination between the HpaI site and the  $\alpha$ -globin locus is essentially zero. Therefore, if the polymorphism is present in heterozygous conditions in a family at risk for sickle cell disease, and if appropriate information exists to establish the linkage relationships between the polymorphic site and the  $\alpha$ -globin alleles in the parents, the restriction fragment polymorphism can be used to predict the  $\alpha$ -globin genotype of the fetus.

Kan and Dozy have calculated that 60% of black families in North America at risk for sickle cell anaemia are amenable to this kind of predictive analysis. Other polymorphisms in or around the  $\alpha$ -globin locus can be used for the same purpose, and serve to increase the number of families which might benefit from the procedure<sup>52</sup>. Geever et al.<sup>53</sup> have recently reported a restriction site change which is directly related to the nucleotide base substitution responsible for the conversion of the wild-type  $\alpha$ -globin gene to the sickle cell anaemia mutated version. In this case, there is a one to one relationship between the restriction pattern and mutant gene, thereby obviating the necessity of testing for linked polymorphisms in family members. Such direct tests for the presence or absence of gene mutations are likely to be the preferred prenatal diagnostic tests of the future.

The  $\alpha$ -globin example must not be taken as a representative case. The biochemical function of the  $\alpha$ -globin complex is known and more than 100 kb of the  $\alpha$ -globin region has been cloned. On the other hand, the biochemical lesions of many disease genes are unknown, and strategies for cloning these genes have not yet been devised. It should be possible to establish linkage between such a disease gene and a restriction fragment marker mendelian mapping, but finding tight linkage relationships of 1 centimorgan or less will be time consuming

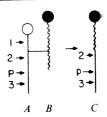

Fig. 3 Breakage-translocation method of establishing gene linkage relationships. A, donor chromosome; B, recipient chromosome; C, translocated chromosome resulting from exchange between the donor and recipient chromosomes. 1-3, Constitutive genes; P, prototrophic gene. The reciprocal rearrangement product bearing the donor chromosome is presumed to be lost.

and costly. On the other hand, a linkage distance in excess of 1 centimorgan is unlikely to be acceptable for prenatal diagnosis, so that in many instances cloning of the disease gene may be a necessary step in developing a prenatal diagnostic test based on the detection of restriction fragment polymorphisms. Alternatively, predictive accuracy can be significantly improved by mapping restriction fragment markers to positions flanking the disease gene. Positive identification of a genetically diseased fetus would then depend on the parental configuration of the outside markers (the non-cross-over class). False negative predictions for the disease gene would in this case result from double cross-overs occurring in the intervals flanking it. However, the error frequency will be small and is a function of the size of the flanking genetic intervals. If the distance between the disease gene and each of the flanking markers was 1 centimorgan the probability of the double cross-over would be 0.0001. The mapping of multiple restriction fragment markers in the vicinity of a disease gene can be accomplished by means of somatic cell genetic procedures referred to above. The availability of numerous, closely linked, flanking markers would increase the probability of detecting the appropriately polymorphic combinations within any given family. Moreover, somatic cell genetic procedures can be used to determine the cis/trans relationship of flanking mankers within particular family members.

### 40Ar/39Ar age spectra from the KBS Tuff, **Koobi Fora Formation**

### Ian McDougall

Research School of Earth Sciences, Australian National University, Canberra, ACT 2600, Australia

 $^{40}Ar/^{39}Ar$  age spectra on anorthoclase phenocrysts from three pumice clasts in the KBS Tuff yield nearly ideal flat patterns, providing good evidence that the samples have remained undisturbed since crystallization. The ages are concordant at  $1.88 \pm 0.02$  Myr, and confirm that the KBS Tuff, a key marker bed in the Koobi Fora Formation, northern Kenya, is now very well dated. These results resolve the conflict between earlier 40Ar/39Ar and conventional K-Ar dating measurements on the KBS Tuff.

THE KBS Tuff is an important marker bed in the Pliocene to Pleistocene sedimentary sequence deposited in a basin centred on lat.  $4^{\circ}\,N, long.\,36.3^{\circ}\,E,$  adjacent to the eastern shores of Lake Turkana, northern Kenya<sup>1-3</sup>. Vertebrate fossils, including hominids, have been found<sup>4-9</sup> in stratigraphic proximity to the KBS Tuff, at the base of which numerous stone tools have been recovered<sup>6</sup>. Thus it is of interest to establish accurately the age of the KBS Tuff, especially in regard to hominid evolution 10. There has been much controversy as to the age of this bed<sup>7-9,11-1</sup>. but recent dating studies on minerals separated from pumice clasts found within the KBS Tuff, have provided relatively consistent ages within the range  $1.85 \pm 0.1$  Myr<sup>13-15</sup>. The most precise age estimate of 1.89 ± 0.01 Myr was based on conventional K-Ar isotopic age measurements on anorthoclase feldspar<sup>13</sup>.

An unresolved problem concerns understanding the meaning of the ages for the KBS Tuff reported by Fitch, Miller and coworkers 11,16-19, who mainly used the 40Ar/39Ar dating technique on anorthoclase separated from pumice clasts. The  $^{40}$ Ar/ $^{39}$ Ar total fusion ages ranged from  $0.52 \pm 0.33$  to  $2.6 \pm 0.3$ Myr, and the step heating measurements yielded complex age spectra, interpreted 11,17-19 as indicating marked disturbance of the anorthoclase subsequent to its crystallization. They suggested that crystallization occurred ~2.48 Myr ago, with deposition in the KBS Tuff shortly thereafter, followed by thermal overprinting at various times, especially at ~1.8 and

Here I present results of dating of anorthoclase separated from three pumice clasts found within the KBS Tuff, using the  $^{40}\mbox{Ar}/^{39}\mbox{Ar}$  total fusion and age spectrum techniques. These data provide strong evidence that the samples have remained undisturbed since crystallization, which occurred 1.88 ± 0.02 Myr ago.

### **KBS Tuff**

The KBS Tuff occurs within an essentially flatlying sequence of sediments, little more than 300-m thick, that crops out adjacent to Lake Turkana over an area at least 80 km (north-south) by 30 km (east–west). The KBS Tuff, commonly  $\sim 1$ -m thick, is the topmost unit of the lower member of the Koobi Fora Formation, and is overlain by no more than 125 m of sediment<sup>1-3</sup>. In common with other tuffs in the sequence, the KBS Tuff was transported by and deposited from water3, and consists mainly of rhyolitic glass with some admixture of early Palaeozoic and Tertiary detrital material.

Locally within the KBS Tuff, pumice clasts are found, regarded as products of the same volcanic eruptions that produced the bulk of the tuff<sup>3</sup>. Pumice clasts are used for the isotopic dating because they are less likely to be contaminated by old detrital material compared with the enclosing tuff. Here I have used anorthoclase separated from three pumice clasts, previously dated by the conventional K-Ar method<sup>13</sup>. Sample 78-1038 is from the KBS Tuff in area 105 (grid ref. HBH $\sim$ 730497), adjacent to its type locality, whereas samples 78-1047 and 79-14 are from a correlative of the KBS Tuff in area 131 (grid ref. HBH ~ 774594), about 10 km north-northeast of the locality for sample 78-1038. Geochemical data<sup>20</sup> from pumice clasts confirm that it is the same tuff in areas 105 and 131, but that the tuff in area 112 which yielded 13 similar K-Ar ages is not likely to be the same bed as the type KBS Tuff.

#### Methods

In the  $^{40}\text{Ar}/^{39}\text{Ar}$  dating method,  $^{39}\text{Ar}$  is generated from  $^{39}\text{K}$  in the sample by fast neutrons in a nuclear reactor, following which Ar is extracted in a high vacuum system and analysed isotopically, allowing simultaneous determination of K and

 $<sup>\</sup>lambda = 5.543 \times 10^{-10} \, \mathrm{yr^{-1}}$ . Errors at level of 1 s.d. All data corrected for instrument discrimination. <sup>37</sup>Ar and <sup>39</sup>Ar corrected for decay. Line blanks have not been applied, but are as follows for <sup>40</sup>Ar: 78-1038 step heat 1, 2.5 × 10<sup>-13</sup> mol; 78-1038 step heat 2, 1.5 × 10<sup>-13</sup> mol; 78-1047 step heat,  $4 \times 10^{-13} \, \mathrm{mol}$ ; 79-14 step heat,  $3 \times 10^{-13} \, \mathrm{mol}$ . Reported absolute amounts have an additional untabulated uncertainty of  $\sim 10\%$ .

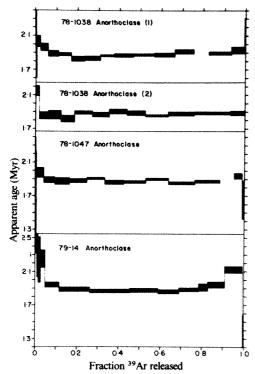

Fig. 1 40Ar/39Ar age spectra for anorthoclase from pumice clasts in the KBS Tuff. Data plotted as apparent age against fraction of 39Ar released. Uncertainty of the age for each step, at the level of 1 s.d., indicated by thickness of bar.

radiogenic Ar (<sup>40</sup>Ar\*) (ref. 21). The ratio <sup>40</sup>Ar\*/<sup>39</sup>Ar is proportional to age. The method is applied in two distinct ways, both of which are used here. First, the sample can be fused after irradiation and from the measured isotopic composition of the Ar an age can be derived, which normally agrees with the conventional K-Ar age. Second, after irradiation of the sample, the Ar can be released in stages by stepwise or incremental heating, commencing at a temperature well below that of fusion, and the gas evolved in successive steps analysed to provide a series of apparent ages. A plot of age versus fraction of <sup>39</sup>Ar released, an age spectrum, may be interpreted<sup>22</sup> in terms of distribution of <sup>40</sup>Ar\* and <sup>39</sup>Ar in the sample.

Anorthoclase should be nearly ideal for  $^{40}$ Ar/ $^{39}$ Ar age spectrum measurements as it remains stable in the vacuum system during much of the heating, so that diffusion is likely to be the major transport mechanism for extraction of Ar. The crystal fragments were kept relatively coarse, in the range  $100-350 \,\mu\text{m}$ , in the hope that if geologically-induced diffusion profiles for  $^{40}$ Ar\* are present, they would be revealed by the age spectrum measurements.

Irradiations for 30 h were carried out in a horizontal facility adjacent to, but not within the core of Hifar reactor<sup>23,24</sup>, where the fast neutron flux is  $\sim 4 \times 10^{12}$  neutrons cm<sup>-2</sup> s<sup>-1</sup>. The cylindrical reactor vessel of internal size ~31 mm (length) by 11 mm (diameter) was lined with Cd to reduce the (40Ar/39Ar) correction factor, measured by analysis of K2SO4 salt, to a low level<sup>25</sup>. Samples were placed in machined Al containers, with only one unknown in each reactor vessel in two separate containers of different size, sandwiched between those in which K<sub>2</sub>SO<sub>4</sub> was placed at either end of the vessel. Centrally located within each anorthoclase sample container was another cylindrical container in which the flux monitor, GA1550 biotite of K-Ar age 97.9 Myr (refs 23, 26), was placed. This geometrical arrangement of flux monitor and sample was developed<sup>27</sup> initially to overcome problems of large neutron flux gradients, but inversion of the reactor vessel at exactly halfway through the irradiation has virtually eliminated this difficulty, so that the neutron fluence can now be measured routinely to better than 1%

Samples for <sup>40</sup>Ar/<sup>39</sup>Ar age spectrum measurements were heated by means of a radiofrequency generator for 45-min

intervals at successively higher temperatures in the Ar extraction system. Temperatures were measured by thermocouple and optical pyrometer; increments between successive steps are probably correct to ~10 °C, but the actual temperatures given in Table 1 are only approximate, because of relatively large temperature gradients over the Mo crucible in which the sample was heated. The gas from each extraction was purified and the Ar transferred directly to a Micromass 12 mass spectrometer. operated in the static mode and at an accelerating potential of 2 kV. Peak hopping, by varying the magnetic field, is used to focus the ion beams on the Faraday cup. Data are taken digitally on-line with a Hewlett-Packard 1000 computer, in which all data reduction is carried out. The amount of gas extracted at each step averaged  $\sim 2 \times 10^{-12}$  mol <sup>40</sup>Ar, giving an ion beam of ~500 mV using a  $10^{11}$ - $\Omega$  resistor in the Cary  $4\overline{0}1$  electrometer. Background in the mass spectrometer was measured routinely but normally was negligible.

Peak height data from the mass spectrometer were extrapolated to the time of admission of the gas into the machine using a least squares procedure and corrections applied for machine discrimination, decay of  $^{37}\mathrm{Ar}$  and  $^{39}\mathrm{Ar}$  and for neutron-induced interfering isotopes. Correction factors applied were: ( $^{36}\mathrm{Ar}/^{37}\mathrm{Ar})_{\mathrm{Ca}} = 3.06 \times 10^{-4}$ ; ( $^{39}\mathrm{Ar}/^{37}\mathrm{Ar})_{\mathrm{Ca}} = 7.27 \times 10^{-4}$  (ref. 25), and ( $^{40}\mathrm{Ar}/^{39}\mathrm{Ar})_{\mathrm{K}} = 0.020 \pm 0.005$ , the average value measured on  $\mathrm{K}_2\mathrm{SO}_4$  during this work. For 78-1047 total fusion only, the value of the K correction factor was 0.066.

#### Results

Data are given in Table 1 as amounts of each Ar isotope, derived from the measured sensitivity of the mass spectrometer. The relative amounts quoted for a given analysis are precise to within the uncertainties, but the absolute amounts may only be accurate to  $\sim\!10\%$ . In a few cases almost all the  $^{37}\mathrm{Ar}$  had decayed before analysis, but as the K/Ca ratio of these feldspars is large (>50), corrections for neutron-induced Ar from Ca are small to negligible. Data in Table 1 are not corrected for line blank, because the blank accounts for more than half the  $^{36}\mathrm{Ar}$  in many analyses, and it is only known to  $\sim\!50\%$ . Information is given in Table 1 so that blank corrected data can be calculated if desired.

Ages listed in Table 1 are calculated on the assumption that the non-radiogenic or trapped Ar in the samples has the composition of atmospheric Ar in which  $^{40}$ Ar/ $^{36}$ Ar = 295.5. These calculated ages are also shown as age spectra in Fig. 1. ' In Fig. 2 data are shown for each step heating experiment on a correlation diagram with <sup>36</sup>Ar/<sup>40</sup>Ar as the ordinate and <sup>39</sup>Ar/<sup>40</sup>Ar as the abscissa <sup>28-30</sup>. If data from a step heating experiment define a good straight line on this diagram, it can be interpreted as a mixing line between non-radiogenic or trapped Ar, represented by a point on the ordinate, and Ar derived from K, represented by a point on the abscissa. Thus the isotopic composition of Ar for each gas fraction plots in Fig. 2 at a point determined by the proportion of the two end members. The intercept of the line with the ordinate defines the <sup>36</sup>Ar/<sup>40</sup>Ar ratio of the trapped component, and the intercept with the abscissa gives the <sup>39</sup>Ar/<sup>40</sup>Ar ratio, the reciprocal of which is proportional to age. This type of correlation diagram is preferred to the more common <sup>40</sup>Ar/<sup>36</sup>Ar versus <sup>39</sup>Ar/<sup>36</sup>Ar plot because problems associated with correlated errors are much less. Results of the regression analyses, using standard techniques<sup>31</sup>, are given in Table 2. In the regressions, the MSWD is a goodness of fit parameter; if this exceeds a value of  $\sim 2.5$  it can be concluded<sup>32</sup> that there is scatter of data points about the line significantly greater than can be accounted for by experimental error alone.

### Discussion

The  $^{40}$ Ar/ $^{39}$ Ar total fusion ages, measured on separate aliquots of the samples, agree well with one another, yielding a mean age of  $1.89 \pm 0.01$  Myr (Tables 1 and 2). In addition, the individual results are concordant with the K-Ar ages measured on the same samples (Table 2).

 $\lambda = 5.543 \times 10^{-10} \text{ yr}^{-1}$ 

(40Ar/34Ar), refers to composition of mitial or trapped Ar

Incremental total fusion ages, calculated from all data obtained during a step heating experiment by combining the ages and errors according to the proportion of <sup>39</sup>Ar in each step, agree satisfactorily with the directly measured total fusion ages, as the errors overlap in all cases (Tables 1 and 2).

Age spectra are shown in Fig. 1, in which the calculated age for each step, together with its error, is plotted against fraction of <sup>39</sup>Ar released. The age spectra are similar to one another and are characterized by flat patterns or plateaus consisting of many steps which yielded essentially concordant ages over most of the release of 39Ar. Data are also shown on the 36Ar/40Ar versus  $^{39}\mathrm{Ar}/^{40}\mathrm{Ar}$  plot in Fig. 2. Table 2 summarizes the results. Plateau and regression ages are derived using all data from each step heating experiment, as well as by excluding results from steps that give discordant ages. The criterion for exclusion of a datum was that the calculated age differed by more than twice its error  $(2 \sigma)$  from that of the plateau. Generally the steps excluded account for only a small proportion of the gas release at the beginning or end of the experiment, and the differences between the results are small (Table 2). Overall the plateau ages and those derived from the regressions form a remarkably concordant set ranging from 1.85 to 1.92 Myr (Table 2).

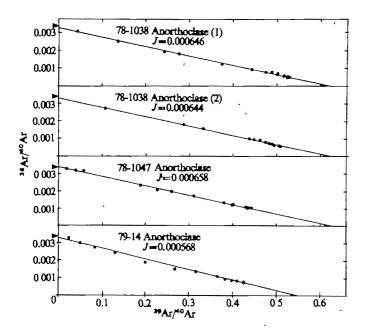

Fig. 2 Correlation diagram showing Ar isotopic composition for each gas fraction of each step heating experiment on anorthoclase from pulmice clasts in the KBS Tuff. A best fit straight line for each experiment is shown intercept on ordinate indicates composition of trapped Ar, and intercept on abscuras gives composition of the K-derived components, the inverse of which is proportional to age ., Isotopic composition of atmospheric Ar as midicated on ordinate

Two heating experiments were undertaken on anorthoclase 78-1038 to examine the reproducibility of an age spectrum. The two age spectra are similar (Fig. 1), each showing a welldeveloped plateau, the ages derived from which agree to within experimental error (Table 2). The second experiment yielded a virtually ideal plateau, comprising data from all steps except the first, which consisted of  $\sim 2\%$  of the total gas and which gave a high apparent age (Fig. 1). A similar effect is seen in the results from the first experiment, but the ages are only marginally high and are distributed over the first three gas fractions comprising ~5% of the <sup>39</sup>Ar. A possible explanation for the high ages for the early part of the release may be that some <sup>39</sup>Ar was lost by recoil from the marginal parts of the crystal fragments<sup>33</sup>. Results from the second experiment indicate that the gas fraction extracted at 1,160 °C, but lost in the first experiment, is unlikely to have given an age very different from those obtained for adjacent steps.

Regression of data from both step heating experiments on sample 78–1038 gave ages systematically slightly younger than the plateau ages (Table 2). This is reflected also in the <sup>40</sup>Ar/<sup>36</sup>Ar values derived for the initial or trapped Ar, the values for which are higher than the atmospheric Ar value of 295.5. These differences, however, are small and not statistically significant, especially when calculated after exclusion of the few discordant results (Table 2). There is greater scatter of the data points about the regression line than can be accounted for by experimental error in the first experiment, but for the second experiment the MSWD value is <2.5, so that all scatter can be attributed to experimental error.

The two anorthoclase samples from pumice clasts in the KBS Tuff correlative in area 131 also yield age spectra exhibiting good plateaus (Fig. 1). Sample 78-1047 has a virtually ideal flat spectrum and all ages derived from the combined data are concordant at 1.88 ± 0.01 Myr, irrespective of the manner by which they are calculated (Table 2). Gas from one step at 1,210 °C, comprising ~6% of the total 39Ar, was lost in the experiment on 78-1047, but it is reasonable to assume that this gas fraction would have given results similar to those obtained from adjacent steps. The other anorthoclase from area 131, sample 79-14, yielded a plateau for more than 85% of the release (Fig. 1), but shows high apparent ages for the first 5% of <sup>39</sup>Ar released and also for most of the last 8% of the release. The data points from this step heating experiment show significant scatter about the regression line, as indicated by the high value for the MSWD (Table 2). Even when the three most discordant points are excluded, there remains scatter in excess of that which can be accounted for by experimental error. If only those data are regressed that form the plateau between 5 and 92% of the 39Ar release, 'a line fitting to within experimental error is obtained (MSWD = 1.8). This regression yields an age of  $1.81 \pm 0.02$  Myr, and a  $^{40}$ Ar/ $^{36}$ Ar value for the trapped component of 362±7, which is statistically significantly different from the value for atmospheric Ar. Such a result conflicts with data from the other samples, and may be quite accidental because all the

points used in this regression plot are in a rather restricted portion of the correlation diagram with values for <sup>39</sup>Ar/<sup>40</sup>Ar between 0.31 and 0.43 (Fig. 2).

The flat 40 Ar/39 Ar age spectra over much of the gas release for anorthoclase from pumices in the KBS Tuff suggest that the distribution of <sup>40</sup>Ar\* in the crystals is relatively homogeneous. This conclusion would be correct if the effective dimension for <sup>40</sup>Ar\* diffusion (see ref. 34) is less than the size of the crystal fragments used in the experiments. Some of the anorthoclase crystals exhibit closely spaced (~2 µm) polysynthetic twins, so that it may be reasonable to propose that the distance between the twin planes is likely to be the effective dimension for 40Ar\* diffusion. Thus the lack of evidence for significant gradients of <sup>40</sup>Ar\* in the feldspar concentrates analysed is interpreted as indicating that closed system behaviour has prevailed in the feldspar since crystallization, at least in respect of the K-Ar

Regression analyses of data from the three anorthoclase samples yield a mean age of  $1.87 \pm 0.01$  Myr, and suggest that the composition of the trapped or initial Ar in the samples is indistinguishable from atmospheric Ar (Table 2). The plateau ages agree at  $1.89 \pm 0.02$  Myr, and the directly measured  $^{40}$ Ar/ $^{39}$ Ar total fusion ages average  $1.89 \pm 0.01$  Myr. An age of  $1.88 \pm 0.02$  Myr is suggested as the best estimate from the <sup>40</sup>Ar/<sup>39</sup>Ar data. This is in excellent agreement with the mean conventional K-Ar age of 1.89 ± 0.02 Myr derived from the results on seven anorthoclase samples analysed from pumices in the KBS Tuff in areas 105 and 131 (ref. 13). The concordancy of all these ages provides strong evidence that the anorthoclase has had a simple undisturbed history since crystallization from a rhyolitic melt. Geological evidence is interpreted<sup>3</sup> as indicating that deposition of the KBS Tuff occurred very soon after the explosive volcanism that produced the tuff and the pumice clasts, so that the measured ages are believed closely to approximate that of deposition. The simple geological history of the anorthoclase subsequent to its crystallization, incorporation in pumice clasts and deposition with the KBS Tuff, is consistent with the evidence that the tuff has never been covered by more than ~125 m of sediment, and with the weakly indurated nature of the sediments in the sequence.

Finally I comment on the previously published 11,16-19 <sup>40</sup>Ar/<sup>39</sup>Ar results on anorthoclase from pumices in the KBS Tuff. The  $^{40}\mathrm{Ar}/^{39}\mathrm{Ar}$  total fusion ages measured on 10 different concentrates, as summarized by Fitch et al. 19, range from 0.53 to 2.48 Myr, typically with quoted errors between 0.1 and 0.5 Myr. The proportion of 40 Ar\* in these analyses generally is <20% of the total <sup>40</sup>Ar and commonly <10% (ref. 18). On the basis of the large scatter in the ages and the small proportion of <sup>40</sup>Ar\* in the gas extracted from the anorthoclase concentrates, I suggest that the results are analytically less precise than given by these authors.

The results of <sup>40</sup>Ar/<sup>39</sup>Ar age measurements by the step heat-

ing method on anorthoclase from KBS Tuff pumices, as reported by Fitch and coworkers 11,16-19, are difficult to evaluate. This is partly because analytical data from only one of the eight experiments have been published. In two other cases a form of age spectrum diagram was given, and several correlation diagrams were shown, but interpretations only are provided for some of the step heating experiments. The authors state that each age spectrum is complex. Ages derived from these spectra range from  $1.10 \pm 0.32$  to  $2.48 \pm 0.01$  Myr (refs 11, 18, 19). They interpret ages of ~2.48 Myr as reflecting crystallization of the anorthoclase, and the various younger apparent ages are attributed to subsequent thermal overprinting or disturbance of the feldspars. As noted previously13, geological evidence for such thermal events is lacking. I suggest that unrecognized analytical difficulties and larger than quoted errors must be invoked to explain these earlier 40Ar/39Ar results.

### **Conclusions**

The  $^{40}\mbox{Ar}/^{39}\mbox{Ar}$  age spectra on the three anorthoclase separates from pumice clasts in the KBS Tuff show well-developed plateaus over most of the gas release. This is interpreted as indicating absence of significant 40Ar\* diffusion profiles in the anorthoclase concentrates, consistent with the geological evidence that the samples are unlikely to have been thermally disturbed since crystallization. The 40 Ar/39 Ar total fusion ages, the plateau ages and those derived from the regressions are all concordant at 1.88 ± 0.02 Myr, in excellent agreement with our<sup>13</sup> earlier conventional K-Ar age measurements. As deposition of the tuff is considered to have occurred soon after explosive eruption of the volcanic material, this age provides a good estimate for the KBS Tuff, which must now be regarded as extremely well dated. Such an age is late Pliocene, as the Pliocene-Pleistocene boundary has an estimated age of 1.7 Myr (ref. 35). The precise, accurate dating of the KBS Tuff, a marker bed in the sedimentary sequence exposed adjacent to and east of Lake Turkana, also provides a similarly precise age for tuff bed H2 in the sequence in the Omo Valley, just north of Lake Turkana, as geochemical data<sup>20</sup> indicate that the two tuffs are likely to be equivalent.

Finally, our work confirms that the 40Ar/39Ar age spectrum method can be used successfully on Pliocene to Pleistocene rocks.

I thank the National Museums of Kenya and the Government of Kenya for facilitating my work there. Special thanks go to R. E. F. Leakey and G. Ll. Isaac, joint leaders of the Koobi Fora Research Project, for encouragement and for field support. A. J. W. Gleadow kindly supplied sample 79-14. I thank M. Cowan and R. Rudowski for mineral separations, and R. T. Davies and the late N. W. Tetley for assistance in the laboratory and with computing respectively. The Australian Institute of Nuclear Science and Engineering provided a grant for the irradiations.

# Early archaeological sites, hominid remains and traces of fire from Chesowanja, Kenya

J. A. J. Gowlett\*, J. W. K. Harris†, D. Walton‡ & B. A. Wood§

\* Research Laboratory for Archaeology and the History of Art, Oxford University, Oxford OX1 3QJ, UK
† Department of Anthropology, University of Pittsburgh, Pennsylvania 15260, USA
‡ Department of Physics, McMaster University, Hamilton, Ontario, Canada L8S 4L8
§ Department of Anatomy, The Middlesex Hospital Medical School, London W1P 6DB, UK

Recent investigations of Lower Pleistocene sites at Chesowanja have yielded in situ Oldowan and Oldowan-like stone artefacts, evidence of fire and a fragmentary 'robust' australopithecine cranium. Burnt clay found at one artefact locality dated to  $>1.42\pm0.07$  Myr is the earliest known evidence of fire associated with a hominid occupation site.

THE promise of the Pleistocene localities at Chesowanja, near Lake Baringo, was first shown in 1970, when a partial cranium of a 'robust' australopithecine was recovered<sup>1</sup>. Subsequent work by the late W. W. Bishop led to the recognition of early stone artefacts<sup>2-4</sup>, and systematic archaeological excavations began in 1978.

The exposed Lower Pleistocene sediments belong to the Chemoigut and Chesowanja Formations<sup>2,3</sup>. The Chesowanja basalt, dated to  $1.42 \pm 0.07$  Myr by K-Ar isotope dating<sup>5</sup>, is an important stratigraphic marker which immediately overlies the Chemoigut Formation and lies beneath the palaeosol member of the Chesowanja Formation.

### Archaeological sites in the Chemoigut Formation

The largest and most informative excavation in the Chemoigut Formation, GnJi 1/6E, was in the northern area (Fig. 1 inset), only 15 m from the most recently discovered hominid site. It covered 40 m², and nearly 1,000 artefacts were found in situ, together with numerous faunal remains, including some complete limb bones. Bovids, equids, hippopotamus and crocodile are all represented among the fossil bones recovered (a fuller report of the fauna will be published elsewhere).

The trench was cut in largely homogeneous compacted clayey silts. The sharply defined distribution of finds suggests that they accumulated in a silting-up channel, which can only otherwise be recognized by occasional grit lenses at its base. The finds have a limited vertical distribution (more than 50% occurring within 20 cm); there is no evidence of size sorting of either artefacts or bone and most of the finds occurred within the silts well above the gritty lenses, suggesting a low-energy environment of deposition. The fresh quality of the artefacts also suggests limited movement after discard. Alteration of the water level, perhaps due to seasonal factors, may have led to down-cutting. followed by infilling with almost identical sediments. This accords well with the view held by Bishop et al.2.3 that the localities represent sedimentation at the margins of a saline lake with a fluctuating water level. A similar abundance of antelope and crocodile remains has been noted in some of the Olduvai Bed I sites which have also been interpreted in terms of a lake margin environment<sup>6,7</sup>. The range of fauna, particularly the presence of hippopotamus and crocodile, suggests periods when the water was quite fresh<sup>7</sup>. Remarkable features in GnJi 1/6E were the flecks and lumps of red mineral matter scattered among the artefacts and bones (Fig. 2). A smaller trench, GnJi 1/5, about 100 m further north, also produced artefacts associated with a scatter of bones.

Excavations were also made in area 2 (GnJi 2) of the Chemoigut Formation, where hominid fossils were found in 1970 and 1974. Artefact scatters occur on the surface, but only one

†Present address: Department of Anthropology, University of Wisconsin, Milwaukee, Wisconsin 53201, USA.

rewarding in situ occurrence, GnJi 2/8, was found. This horizon, which occurred only about 15 m from the hominid found in 1970, was close to the surface and could not be followed further laterally because of modern erosion gullies. Area 4 of the Chemoigut Formation contains at least one site (not yet investigated), but area 3 has yielded no finds.

### Sites in the Chesowanja Formation

The Chesowanja basalt is exposed to the east of the Chemoigut Formation. It plunges steeply to the east and is overlain by the palaeosol member of the Chesowanja Formation (Fig. 1, GnJi 10). Its upper surface slopes gently to the west and is sealed in by fine-grained bedded tuffs. These were mapped as belonging to the Karau Tuffs², which outcrop extensively to the west of Chesowanja, but further work has shown that they are a separate local unit, and hence as yet undated (A. Hill, personal communication).

Small artefacts were widespread on the surface of area 10, especially near exposures of the tuffs. Two trenches (GnJi 10/4 and 10/5) revealed dense concentrations of artefacts in the top  $50\,\mathrm{cm}$  of the Chesowanja Formation palaeosols, immediately underlying the tuffs.

In excavation GnJi 10/5, about 1,500 artefacts were found in situ in an area of 25 m<sup>2</sup>. Bone fragments included fish and crocodile remains.

The density of finds and the thickness of the horizon, which included lenses of sand stratified in the clayey palaeosol, suggest that the hominids returned to the locality over a considerable period. Some of the artefacts are abraded, probably due to prolonged surface weathering, possibly from physical transport by water. One such abraded artefact had been retrimmed freshly on one surface and is strong evidence for recurrent use of a site.

In area 10, the artefacts originally discovered in 1973 included Acheulean bifaces<sup>1-3</sup>. However, bifaces are absent from the *in situ* assemblages excavated in 1978, but have been found on the surface immediately above the bedded tuffs. Trial trenches demonstrated that a later channel had cut through the bedded tuffs, down into the Chesowanja Formation palaeosols. Bifaces were found on the surface of the channel fill, where one small specimen was recovered *in situ*. Thus the bifaces are clearly of much later date and should not be considered components of the Chesowanja Formation industry.

### Affinities of the stone industries

The assemblages from the Chemoigut Formation can be assigned to the Oldowan industrial complex<sup>6</sup>, in the broadest sense. We previously assigned surface collections to the Developed Oldowan<sup>4</sup>, but the finely shaped discoids which prompted this designation may be explained partly by the especially tractable nature of the fine-grained lavas used in stone-working. Such specimens are not common in situ and the general character of the artefacts is compatible with material from Olduvai Bed I/Lower Bed II<sup>6</sup> (Fig. 3). Thus it is appropriate to designate this

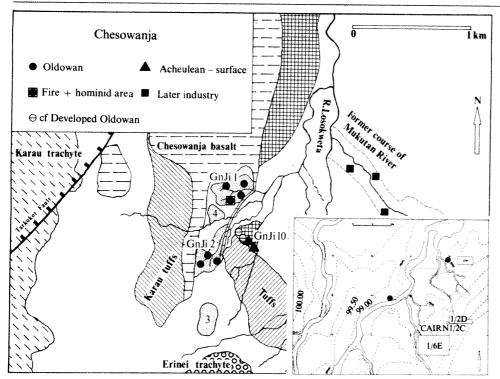

Fig. 1 Locality map of Chesowanja (compare with ref. 3, Fig. 20:1). 
Chemoigut Formation exposures; 
Chesowanja Formation palaeosol. Later sediments are not distinguished on the map. In the inset; 
, hominid remains; 
, modern gulley edges; ----, contours at 50-cm intervals. Scale, 10 m between crosses.

as the Chemoigut Industry within the Oldowan complex. One crude biface, made from an elongated cobble, was isolated on the surface of the Chemoigut Formation, but this is not insufficient basis for postulating the existence of a contemporary Acheulean facies. Finished tools from the Chemoigut Formation are on average slightly larger than those from the Olduvai<sup>6</sup> or Karari<sup>8</sup> industries, but the assemblage from GnJi 2/8 does include small forms. Technologically, the artefacts are broadly comparable with those found on the Karari sites, but they do not include the high-backed heavy-duty scrapers characteristic of the Karari Industry.

The industry from the Chesowanja Formation is also made mainly on lava, but some pieces are fashioned from welded tuff. The artefacts are strikingly small, and only 10 of more than 60 shaped tools weigh > 50 g. The size of the artefacts was

apparently not constrained by the availability of raw materials, for lava must have been abundant locally. Due to its distinctive characteristics and stratigraphic position, we define this material as the Losokweta Industry (after a local river) and in purely descriptive terms regard it as 'cf. Developed Oldowan'.

The new stratigraphic observations suggest a much later date for the Acheulean artefacts<sup>3,4</sup>. They seem to resemble artefacts from the Kapthurin Formation<sup>9</sup> more closely than those from sites in the Baringo basin such as Kilombe<sup>10</sup>.

### New hominid evidence from Chesowanja

Fragments of a hominid cranium, KNM-CH 304, were discovered in two separate scatters, 15 m apart (Fig. 1), by Bernard Ngeneo and Wambua Mangao in 1978. The specimen consists of five cranial vault fragments labelled A-E. A is a fragment of

occipital which includes lambda, inion and most of the left side of the occipital squame up to, and including, asterion; the surface bone is cracked and eroded. B is the left parietal including bregma, part of the coronal suture and a length of sagittal suture and parasagittal crest; C is the left temporal squame; D the right parietal including pterion and part of the squamosal suture; and E a small fragment of right parietal. Table 2 gives the length and thickness of A, B and relevant comparative material.

The most obvious diagnostic features of the cranium are ectocranial crests. The fused sagittal crest is 3 mm high at bregma, but 30 mm posteriorly it splits into two parasagittal crests which, at their highest point, project 11 mm from the vault surface. They continue onto the occipital bone where, about 20 mm posterior to lambda, they each turn abruptly laterally and fuse quite close to the midline with the nuchal crest to form a compound nuchal crest. The nuchal crest on the left side divides near to asterion and the inferior limb fuses with a separate crest running along the occipitotemporal suture. There is a small 'bare area' between inion and the point where the parasagittal crests diverge. Other features useful for taxonomic diagnosis are a series of coarse ridges and furrows which run anterolaterally from the sagittal suture in the direction of pterion; fine striae which mark the parietal bone just superior to the squamous suture and a pattern of venous sinus grooves on the endocranial surface of the occipital fragment, suggests that the main drainage pathway for venous blood was via an occipital venous sinus.

The combination of an anteriorly situated sagittal crest and a compound nuchal crest is shared with only one other fossil cranium, OH5, the type specimen of Australopithecus bolsei<sup>11</sup> from Olduvai Gorge Tanzania. In another adult cranium belonging to the same taxon, KNM-ER 406, there is a substantial sagittal crest, but apparently no compound nuchal crest. In a juvenile cranium, L338y-6, from the Omo, the inferior temporal and superior nuchal lines nearly touch the left side whereas the inferior temporal lines are still 12 mm apart some 27 mm posterior to bregma<sup>12</sup>. Thus, if this individual had reached adulthood, a substantial compound nuchal crest would probably have been present. The adult skull KNM-ER 1805 from Koobi Fora, which still awaits formal attribution to a taxon, combines a compound nuchal crest with a sagittal crest, but in this case the sagittal crest is situated more posteriorly. It begins 30 mm posterior to bregma, and at stephanion the distance between the inferior temporal lines is at least 31 mm. The cranial vault morphology of fossils attributed to Australopithecus africanus suggests that sagittal crests may have occurred in some specimens, but there is no evidence that any of these crania had developed a compound nuchal creet.

The coarse ridges which mark the parietal are like those described by Tobias<sup>11</sup> in OH5, and similar features are also seen in KNM-ER 406. Finer striae—striae parietalis—are also

present on OH5, KNM-ER 406 and L338y-6. Rak<sup>13</sup> has carefully analysed these markings and he relates them to a special type of overlapping squamosal suture which has only been found in crania attributed to A. bolsei. The pattern of venous sinus grooves, with a dominant occipital sinus, resembles that seen in OH5, SK 859 and SK 1585<sup>14</sup>, and a similar pattern is suggested by the preserved morphology in SK 46<sup>15</sup>. However, at least one East African 'robust' australopithecine specimen, L338y-6, has the more usual human pattern<sup>12</sup> (but Holloway<sup>16</sup> is cautious about attributing this specimen to A. bolsei). Occipital sinus dominance is therefore best considered indicative, rather than diagnostic, of A. bolsei.

Thus, although the new cranium is fragmentary, sufficient diagnostic areas are preserved to attribute it with some confidence to A. bolsei, thereby confirming the presence of this hominid at Chesowania.

This specimen fails to provide any new support for the proposal of Carney et al. that the only other cranium known from Chesowanja, KNM-CH 1, represented an 'evolved' form of 'robust' australopithecine. Of the three possible features cited by these authors—a larger brain, a more flexed skull base and the reduction or refinement of masticatory apparatus—the new specimen is only complete enough to provide information about the last. The ectocranial crests suggests that the masticatory

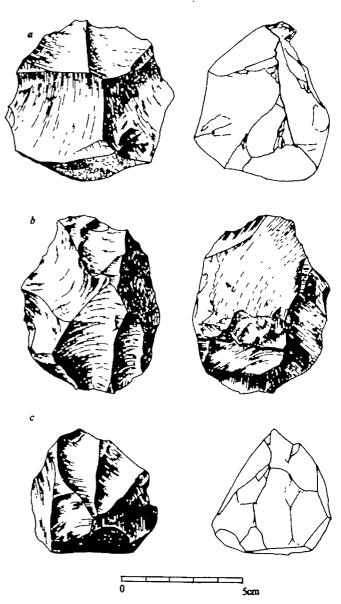

Fig. 3 Artefacts from the Chemoigut Formation. a, Chopper, b, discoid; c, polyhedron.

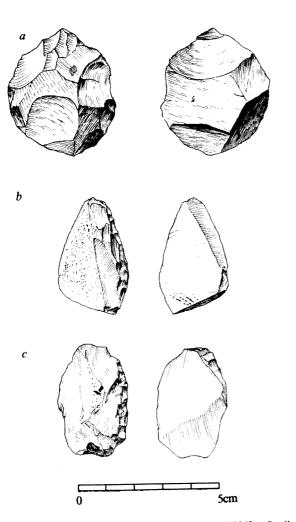

muscles in KNM-CH 304 were at least as well developed as they were in the two much better preserved 'robust' australopithecine crania from East Africa, KNM-ER 406 and OH5.

### Evidence and implications of fire

The possession of fire is a major component of cultural behaviour, and is universal in recent times even among hunters and gatherers. Evidence for fire is relatively common on later Acheulean sites<sup>17</sup> ( $\sim 0.2$ –0.3 Myr), but rare in earlier sites; Vertesszöllos<sup>18</sup> (Hungary), Arago<sup>19</sup> (southern France) and Choukoutien<sup>17</sup> (China) are the main examples and none of these is believed to be older than 0.5 Myr.

If, however, fire had been used on earlier sites, evidence for it might have vanished. Isaac<sup>20</sup> noted that the fine charcoal remaining from wood fires is easily degraded in tropical conditions and readily removed by wind and water. Thus on open sites, baked material is likely to provide the best evidence of fire. Inconclusive evidence for fire has come from magnetic and thermoluminescence (TL) analysis of material from reddened areas of ground at site FxJj 20 East<sup>21</sup> on the Karari escarpment at Koobi Fora (~1.3-1.5 Myr) and from palaeomagnetic determinations on cobbles at an Acheulean site at Gadeb in Ethiopia<sup>22</sup>.

At Chesowanja, over 40 pieces of 'burnt clay' were found on the GnJi 1/6E site. They range in size from tiny flecks to lumps 5-7 cm across. They were thoroughly intermingled with the artefacts and bones (Fig. 2) and did not occur without this association. They could not have been introduced into the site after its formation. Samples of the supposed burnt material were

**Fig. 4** Artefacts from the Chesowanja Formation, site GnJi 10/5. a, Small discoid; b c, scrapers.

Table 2 Measurements of KNM-CH 304 and relevant comparative material KNM-CH 304 OH5 KNM-ER 406 Parietal Sagittal chord 80 76 Thickness at bregma Thickness at asterion Occipital Inion-left asterion chord 52 38 Lambda-inion chord Thickness at lambda 10 7.0 Thickness at asterion 14.5 7.0

All measurements are in mm and, except those marked\* taken from ref. 11, were taken by BAW

examined by one of us (D.W.). One sample possessed a magnetic moment of the order of  $10^{-4}\,\mathrm{A\,m^2\,kg^{-1}}$ , which is broadly comparable with the magnetic moment of more recent samples of burnt clay  $^{23,24}$ . On heating and cooling in zero magnetic field, the moment disappeared at  $400\,\mathrm{^{\circ}C}$ —a normal temperature for open camp fires, which seldom exceed  $700\,\mathrm{^{\circ}C^{25}}$ .

Alternatively, the baked material could have resulted, not from a controlled camp fire, but from a 'wild' bush fire. However, although these create transient surface temperatures of up to 700 °C, the temperature then falls away rapidly below the surface<sup>26</sup>, so that baking of clay would be unusual. Investigations of baking around a recently burned tree stump near Chesowanja showed that the temperature was at least 200 °C higher than that of the fire at GnJi 1/6E<sup>21</sup>.

Thus, although the magnetic evidence is not in itself conclusive, it nonetheless strongly suggests that the Chesowanja clay was burned by a small, controlled fire. Future studies of the cooling rate may provide more specific evidence about its size. A possible explanation for the distribution of the detached lumps of burnt clay is provided by analogy with a later prehistoric hearth observed by one of us (J.A.J.G.) at Kilombe. A fire had baked the underlying sediments, which are now being removed by modern erosion. The burnt clay, being more resistant, was raised slightly above its surroundings, but was cracking and breaking up, and lumps of it were scattered for several metres downslope from the source.

Although natural phenomena such as bush fires, lightning strikes and even volcanic heating could explain the burnt clay at Chesowanja, we are convinced, from examination of the whole occurrence in situ, that hominid activity is a much more likely explanation. Thus, the new find, together with the more tentative evidence from other sites, greatly strengthens the hypothesis that by 1.4 Myr hominids were using and controlling fire.

### **Conclusions**

At Chesowanja hominid remains of robust australopithecines have now been found close to archaeological finds at two separate localities almost 1 km apart. This association must be considered more than coincidental. At both sites non-hominid bones and bone fragments are closely associated with the artefacts, and it is likely that the artefact makers also consumed the meat.

The detailed dietary preferences of these robust australopithecines are not known, but preliminary evidence from studies of tooth microwear suggests that meat was not a significant component of their diet<sup>27</sup>. The Chemoigut Formation sites are approximately contemporary with early specimens of *Homo erectus* found elsewhere in Africa<sup>28</sup>. H. erectus was apparently responsible for the use of fire at Choukoutien and the use of fire by early representatives of the same hominid type at Chesowanja seems to us the most reasonable hypothesis. The principal alternative would involve the robust australopithecines being not merely meat-eaters, but also stone-tool makers and fire-users; we believe that the evidence is strongly against such a view.

If we accept the former hypothesis, then the presence of robust australopithecine fossils at both of these localities is difficult to explain on any basis except a chance association, or that their remains were brought to the site, along with those of other animals, by the makers of the artefacts.

The paucity of evidence bearing on these hypotheses underlines the necessity of locating and investigating new sites of the same period where there is well preserved and in situ evidence of hominid occupation

### Structure of the pro $\alpha 2(I)$ collagen gene

### John Wozney', Douglas Hanahan, Valerie Tate, Helga Boedtker & Paul Doty

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

Fifty-four kilobase pairs (kbp) of cloned chicken DNA containing the entire 38-kbp pro  $\alpha 2(I)$  collagen gene have been isolated and characterized. DNA sequence analysis of a select 4 kbp of the gene has precisely described 14 exons which comprise one-third of the sequences encoding the triple-helical domain of the collagen protein. These exons range in size from 45 to 108 base pairs (bp), are all multiples of the 9 bp that code for the repeating triplet, Gly-X-Y, and have an average size of 70 bp. About 50 introns interrupt this gene. Nevertheless, introns do not separate the coding sequences for the ends of the central triple-helical structural domain and the ends of the propeptide domains.

THE collagens are a set of closely related proteins which provide the extracellular framework responsible for the structural integrity of nearly every organ and tissue in vertebrates. The correctly programmed spatial and temporal regulation of the production of collagen molecules is critical for growth and development. Therefore, the genes which encode these strategically important molecules deserve detailed investigation. Our investigations and those elsewhere have concentrated on the genes which encode the two chains that make up type I collagen, the most abundant of the collagen family.

The major part of the mature collagen consists of three polypeptide chains, called  $\alpha$ -chains, arranged in a long rod-like helical configuration. This region contains about 338 repeats of the amino acid triplet Gly-X-Y, where X and Y are often proline and hydroxyproline. Each polypeptide chain is synthesized as a propeptide with nonhelical regions at both the amino- and carboxy-terminal ends; the propeptides are removed by specific endopeptidases, leaving much shorter nonhelical regions, termed telopeptides, attached to both ends of the collagen helix. Five different types of collagen have been identified: they are made up from nine  $\alpha$ -chains which thereby require nine different genes1.

Recombinant DNA technology has made possible the isolation and structural analysis of several dozen unique eukaryotic genes. With the exception of the interferon genes, all unique genes in vertebrates have been found to contain noncoding sequences (introns) which interrupt their coding sequences (exons). The number of introns ranges from a single intron, as in the rat insulin I gene<sup>3</sup>, to many introns, as in the Xenopus laevis vitellogenin gene which has 33 (ref. 4).

Our preliminary studies of the structure of the chicken pro  $\alpha 1(I)$  and pro  $\alpha 2(I)$  collagen genes, using actinomycin D/CsCl gradients and genomic DNA Southern blotting techniques, indicated that both these collagen genes would contain many introns5. This was dramatically confirmed for both the sheep and chicken pro  $\alpha$ 2 collagen genes by electron microscopy studies of gene clones hybridized to procollagen mRNA. Almost 40 introns, ranging in size from <100 bp to >2,000 bp, could be clearly identified in the electron micrographs of gene clones spanning the entire chicken pro \alpha 2 gene reported by Ohkubo et al.<sup>6</sup>. Seventeen introns were similarly identified in gene clones containing 60% of the sheep pro  $\alpha 2$  gene<sup>7</sup>. Thus, the pro  $\alpha 2$ collagen gene has emerged as the most highly interrupted gene so far examined.

To investigate the intron-exon structure with precision, extensive sequence determinations are required. We have reported the DNA sequence analysis of seven exons in the helical region, ranging in size from 45 to 108 bp8. All are multiples of 9 bp coding for the repeating Gly-X-Y collagen triplet and each begins with the codon for glycine and ends with the codon for the Y residue. The exon sequences reported by Yamada et al.9 have this same characteristic. However, the structure of the carboxy-terminal propeptide is quite different: we found the four exons there to be much larger, ranging in size from 189 to 444 bp8.

We report here the detailed structural analysis of 4 kbp of the collagen gene including the DNA sequence at both the amino-

<sup>\*</sup> Present address: Center for Cancer Research, E17-336, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, Massachusetts 02139, USA.

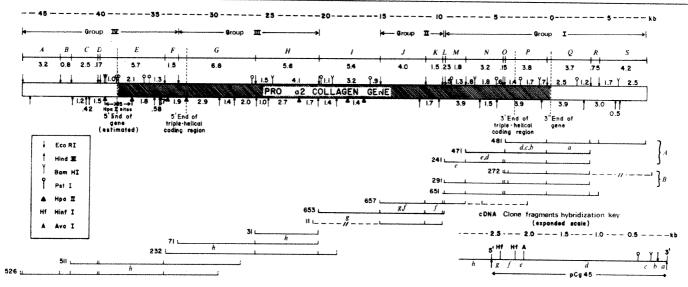

Fig. 1 Restriction endonuclease map of pro α2 collagen gene clones from chicken (Gallas domesticus). Clones containing EcoRI fragments I-S were isolated by hybridization to the cDNA clone pCg45 (ref. 25), those containing fragments G and H by cross-hybridization to pCg45 and those containing fragments A-F by hybridization to the EcoRI-HpaII fragment at the 5' end of EcoRI fragment G. As described previously<sup>8</sup>, the location and orientation of each of the clones were determined by hybridization of the clones digested with various restriction endonucleases to nick-translated fragments of pCg45 labelled a to g in the hybridization key. Fragment h refers to hybridization to kinased procollagen mRNA sequences not contained in pCg45. Vertical lines in the individual clones indicate EcoRI sites; dotted vertical lines indicate synthetic EcoRI sites generated by the linker molecules used in the construction of this λ library<sup>26</sup>.

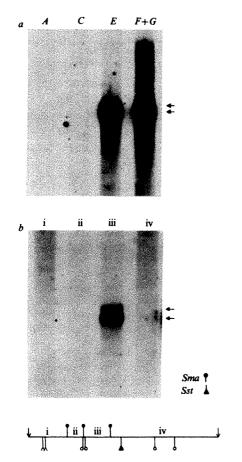

Fig. 2 Location of the 5' end of pro  $\alpha$ 2 collagen gene. Calvaria mRNA was isolated, glyoxylated, electrophoresed on 1% agarose gels and blotted onto nitrocellulose as described by Thomas<sup>27</sup>. Isolated fragments were nicktranslated and hybridized to lanes cut from the RNA blots. a, The EcoRI fragments used as probes are indicated above each lane (see Fig. 1 for locations of fragments). Arrows indicate positions of pro  $\alpha$ 2 collagen mRNAs, located by hybridization to cDNA clone pCg45. The blot was overexposed to confirm lack of coding sequences in EcoRI A and C. The origin of the weaker, upper band is undefined, but may represent alternatively processed molecules or a stable precursor. b Shows hybridization to isolated subfragments of EcoRI E, the origins of which are shown below in the restriction endonuclease map of the fragment. Symbols as in Fig. 1. Hybridization to the Smal-EcoRI subfragment iv is extremely weak, suggesting that there is little coding sequence in this fragment.

and carboxy-terminal junctions of the helical and propeptide coding regions of the gene, the DNA sequence of seven exons near the central portion of the gene which code for contiguous parts of the protein (residues 175-360) and the location, by DNA sequence analysis, of four other exons coding for residues 4-72.

### Isolation of DNA fragments

We have previously reported the isolation of recombinant A clones containing  $\sim 80\%$  of the pro  $\alpha 2(I)$  collagen gene, and have described in detail the structure of the 3' portion of this gene8. We have now isolated overlapping clones which can be arranged into a 54-kbp piece of contiguous genomic DNA containing the entire pro  $\alpha$ 2 collagen gene. Figure 1 shows a partial restriction map of this DNA region, along with some of the  $\lambda$  clones which together span the gene. The cloning strategy is detailed in the Fig. 1 legend. The 5' end of the gene was located at the position indicated in Fig. 1 by two independent methods. Hybridization of labelled EcoRI fragments from the gene clones to procollagen mRNA indicated that the 5' end was probably located in fragment E, because positive hybridization was not obtained with any fragment lying 5' to this region (Fig. 2a and unpublished observations). Subdivision of fragment E with restriction enzymes and the use of these fragments to probe blots of procollagen mRNA enables us to locate the 5' end of the gene (Fig. 2b). These experiments do not rigorously exclude the possibility that there is another exon lying >8.3 kbp 5' to this region, nor that RNA transcription initiates at some point 5' and is so rapidly processed that it is not detected. However, the placement of the 5' end of the gene in this region is consistent with the results of in vitro RNA transcription using truncated gene clones as templates in the Manley 10 cell-free extract system (V.T., unpublished observations). This result, together with the hybridization experiments, place the 5' end of the pro  $\alpha$ 2 collagen gene at the point indicated in Fig. 1. The 5 kbp of coding sequence for the pro  $\alpha$ 2 collagen mRNA is thus spread over a total of 38 kbp of genomic DNA.

#### Triple-helical coding sequences

Although electron microscope studies of mRNA-DNA hybrids may provide an overall picture of exon-intron arrangements in the pro  $\alpha 2$  collagen gene, only DNA sequence analysis can establish the exact size and coding capacity of the exons and the precise location of specific coding regions in the gene. As the

coding information of the gene is so dilute, it is necessary to locate DNA fragments which contain coding information in order to concentrate DNA sequence analysis where it is most valuable. Such regions were identified by hybridization to cloned cDNA or kinased procollagen mRNA and the locations determined more precisely by the use of restriction enzymes which cut sequences predicted to be abundant in the collagen triple-helical region but relatively infrequent elsewhere (see Fig. 4 legend).

The DNA sequences from the 5' end, the 3' end and central portions of the helical region of the pro  $\alpha$ 2 collagen gene were then determined. Fifteen exons, including seven reported previously8, have been located (Fig. 3). The residue numbers of the amino acids in the triple-helical region coded for by each exon are given below. Figure 4 shows the DNA sequence of the genomic region containing the exons coding for residues 175-360 of the triple-helical region. Figure 4a displays the entire sequence of the 1.8-kbp HpaII-EcoRI fragment located at the 3' end of EcoRI fragment H (Fig. 1), while the sequencing scheme used is shown below. This fragment is seen to contain five exons which together encode residues 175-309. Figure 4b displays the DNA sequence of a region of EcoRI fragment I together with the sequencing scheme. Two exons are indicated, coding for residues 310-360. The seven exons contained within the sequences given in Fig. 4 thus code for contiguous parts of the protein (these exons are numbered 29-35 in Fig. 6.)

The DNA sequence determination of 14 complete exons coding for the triple-helical region has further detailed the remarkable structure of the pro  $\alpha 2$  collagen gene: it contains a very large number of exons, each with a correspondingly small amount of coding information; each exon is a multiple of the 9 bp which code for the repeating collagen triplet (Gly-X-Y). Of these 14 exons, 2 contain 45 bp, 7 54 bp, 3 99 bp and 2 108 bp. Although the most frequent exon size is 54 bp, it represents a total of only 7 out of the 14 exons. This contrasts with previous reports that all the exons in this gene contain 54 bp.

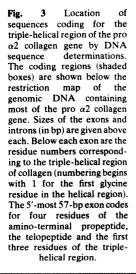

The seven exons coding for residues 175-360 of the triplehelical region show an interesting alternation between large and small exons: 99-45-99-54-108-54-99. This pattern may be extended by including sequence determinations of two additional exons by Yamada et al.9. Exons coding for residues 379-411 (99 bp) and 412-429 (54 bp) were found; an exon of 54 bp, coding for 361-378, therefore almost certainly exists between these two exons and the seven exons whose sequence is given in Fig. 4. This would extend the alternating pattern to 10 exons, coding for 25% of the helical region. Such a pattern may well also exist in the 3' portion of the molecule, but it is clearly absent in the 5' end of the helical coding region of the gene. There is no obvious explanation for this alternating pattern nor why exons of other multiples of 9 bp are not found. Structural domains within the  $\alpha$ 2 triple-helical region of sizes D (234 residues), D/6 (39 residues), D/11 (21 residues) and D/13 (18 residues) have been proposed on the basis of intra-chain amino acid sequence comparisons<sup>11</sup>. Although the latter domain size is the same as the most prevalent exon size, the fact that about half the exons encode 15, 33 or 36 residues indicates that there is little correlation between the exons and structural domains in the helical region.

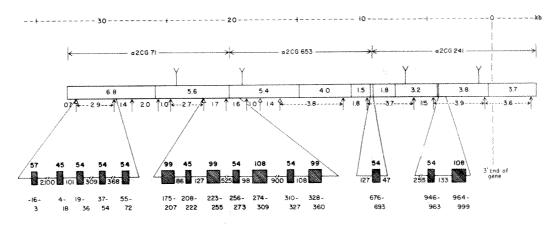

The finding that the triple-helical coding region of the pro  $\alpha 2$ collagen gene contains many small exons, each encoding a multiple of the Gly-X-Y repeat, suggests that the gene may have evolved by duplication. As seven of the eight exons first sequenced were reported to be 54 bp long, Yamada and coworkers proposed that the ancestral collagen gene was 54 bp and that during evolution this gene was duplicated to give rise to the present structure9. In this scheme, the large present-day collagen gene was formed by recombination between introns, followed by additions and deletions of 9 bp. The fact that only 7 of the 14 exons reported here are of 54 bp suggests a different mode of evolution for the collagen gene. If an ancestral triplehelical region gene of 54 bp is assumed, duplication by recombination between intergenic regions or introns (depending on the presence or absence of the propeptide coding regions) could indeed give rise to several 54 bp units. However, inasmuch as introns appear to be free to diverge rapidly, as compared with coding regions, recombination between different introns would be expected to be infrequent. Therefore, the repeating nature of collagen would make homologous recombination between different exons a far more likely event. We suggest that it is most likely that duplication took place in large part by recombination between exons (homologous unequal crossing over) rather than between introns. At each recombination point the exon size could change, readily accounting for exons differing from 54 bp. Recombination between two exons at non-identical positions within the 9 bp coding for the Gly-X-Y repeat would result in disruption of the helical structure of collagen, and thus be deleterious or fatal. Therefore, the exon sizes would always be maintained as a multiple of 9 bp.

### Structural domain junctions

The DNA sequences of the exons coding for both the aminoand carboxy-terminal ends of the triple-helical region have also been determined. In both cases, these exons also code for the telopeptides and parts of the propeptides (Fig. 5). The exon at the amino-terminal end codes for the last 4 residues of the propeptide, all 12 residues of the telopeptide and the first 3 residues of the triple-helical region.

Although the amino acid sequence of the chicken aminoterminal propeptide has not been determined, this sequence is known for calf pro  $\alpha 1$  collagen<sup>12</sup>. The amino acid sequence around the amino-terminal propeptidase cleavage site for pro  $\alpha 1$  collagen is Asn-Phe-Ala-Pro $\downarrow$ Gln. The DNA sequence of the amino-terminal junction exon (Fig. 5) yields a similar

### 481 TTCATTTCTTTAGTAATCTGGTGGCATCTAATTGCCTTGGCCATGG

Fig. 4 a, DNA sequence of the 1.8-kbp Hpall-EcoRI fragment at the 3' end of the EcoRI fragment H (coding for residues 175-309). b, DNA sequence of part of the 2.4-kbp *EcoRI-HpaII* fragment at the 5' end of the *EcoRI* fragment 1 (coding for residues 310-360). The sequencing schemes are shown below the DNA sequences. DNA sequences

were determined by the method of Maxam and Gilbert<sup>28</sup>. Triple-helical coding sequences were located by restriction of isolated gene fragments with *Bst*NI (an isoschizomer of *Eco*RII) and *Sau*96l. From the DNA sequences of the pro a2 collagen triple-helical region determined from the cDNA clones, many of the Pro-Gly sequences of collagen will contain BstNI sites, CC(A/T)GG. Sau961 recognizes the sequence GGNCC, which is also predicted to be very common in the triple-helical coding regions as collagen has many Gly-Pro sequences. The BstNI and Sau961 sites identified by DNA sequence determinations are indicated on the last two lines of the restriction map in a. All 13 BsfNI sites in this 1.8-kb fragment of DNA can be seen to fall within the collagen coding sequences (indicated by the shaded boxed above), while 16 of the 18 Sau961 sites also lie within coding regions. Thus, the correlation of these sites with triple-helical coding regions is excellent. The amino acid sequence for residues 175-327 of chicken  $\alpha$ 2 collagen has not been determined; however, the calf collagen sequence is known<sup>29</sup>. Of the 153 residues determined by DNA sequence analysis here, 133 are identical to the calf sequence, indicating an 87% homology. Only one instance was noted where the DNA-derived amino acid sequence analysis nere, 133 are identical to the can sequence, indicating an 67% nonlongly. Only one instance was noted where the DNA-derived amino acid sequence differs from that determined by amino acid sequencing of chicken  $\alpha 2$  collagen. The DNA sequence indicates that residues 339 and 341 are valine and alanine, whereas the reverse was found by amino acid sequencing. Although it is possible that this represents an allelic difference, the discrepancy may be due to an error in the amino acid sequence determination, as the lack of a thermolysin site which should exist preceding the valine residue was noted when the protein sequence was presented.

Fig. 5 DNA sequences of the genomic regions containing the exons coding for the ends of the helical region. Propeptide coding regions are indicated by open boxes, telopeptide coding regions by solid boxes and triple-helical coding regions by shaded boxes. The amino-terminal junction exon codes for the last 4 residues of the propeptide, all 12 residues of the telopeptide and residues 1–3 of the helical region. The carboxy-terminal junction exon codes for residues 1,000–1,014 of the helical region, all 15 residues of the telopeptide and the first 53 residues of the propeptide. Splicing probably occurs within the last glycine codon. The 112-bp HpaII fragment within the carboxy-terminal junction exon is present in both the gene clones and cDNA clones; its sequence was determined only from the cDNA clone<sup>31</sup>.

sequence for the presumptive propeptidase cleavage side: Asn-Phe-Ala-Ala $\downarrow$ Gln. As no homology can be found between the calf propeptide amino acid sequences located 5' to these in calf and the amino acid sequence which would result from the chick DNA sequence in this region, and as a CAG (the canonical splice junction sequence, see below) immediately precedes the codon for Asn, this exon presumably starts with the above conserved pentapeptide sequence. The following 14 residues, which include the first 3 residues in the triple-helical region, are indentical with the amino acid sequence derived from chick skin  $\alpha$ 2 collagen<sup>13</sup>. At the carboxy-terminal end<sup>8</sup>, the situation is similar except that larger portions of the propeptide and triple-helical coding regions are included in the exon coding for the telopeptide: a single exon codes for 15 residues of the helical region, all 15 residues of the telopeptide and the first 53 residues

of the propeptide. That these three structural domains (at both ends of the collagen molecule) are not separated by introns, as might have been expected, may possibly be explained in that they consist of a specific functional domain, namely the endopeptidase cleavage site.

### **Intervening sequences**

The 19 exons whose DNA sequences have been determined provide an equal number of intron-exon junction sequences (Table 1). In the triple-helical region, there is always an ambiguity as to the precise splice point due to the duplication of Gs at each end of the intron and there is a special problem in defining the exact splice points in the region which codes for the carboxy-terminal propeptide; three nucleotides at both junctions of exon

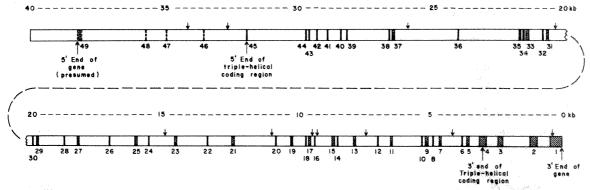

Fig. 6 Location of coding sequences in the pro α2 collagen gene. Forty kilobases of genomic DNA containing the pro α2 collagen gene are represented by two bars, both oriented 5' to 3' (left to right). Exons are indicated by vertical bars, numbered 1 to 49 (3' to 5'). The four exons at the 5' end of the gene have been identified only by electron microscope visualization of RNA-DNA hybrids by Ohkubo et al.6, and are thus indicated by dotted lines. The exon sizes in the helical region whose DNA sequences have not been determined have been indicated such that the small-large alternating pattern extends from exon 38 to exon 5; this is consistent with electron microscope measurements. Arrows (↓) indicate EcoRI sites. Exons whose DNA sequences have been determined are as follows. In this article and ref. 8: exon numbers 45 (amino-terminal structural domain junction); 44-41 (residues 4-72); 35-29 (residues 175-360); 16 (residues 676-693); 6 and 5 (residues 946-999); 4 (carboxy-terminal structural domain junction); 3, 2 and part of 1 (carboxy-terminal propeptide). By other researchers 2: 43-41 (residues 19-72); 27 and 26 (residues 379-429); 10 (residues 838-855); 9 (residues 856-891); 8 (residues 892-909). Only the ends of exon 9 have been sequenced, and therefore it has not been established whether this is one or two exons.

17 are duplicated at the adjacent exon junction, so that four splice points are possible. The splice points in Table 1 have been aligned so that they conform with the GT---AG rule<sup>14</sup>; this requires splicing within the glycine codon at the ends of exons 16/17. With the sequences aligned in this manner, 11 introns begin with GTAAGT, and 7 others differ from this by a single base change. Eighteen introns end with (C/T)AG. These sequences agree well with those found for other eukaryotic genes and are indeed homologous to the 5' part of the U1 RNA which has been proposed to be involved in the splicing process<sup>15,16</sup>. Because every exon in the triple-helical region starts with a glycine residue, the first nucleotide in each is a G, as is usually found in other eukaryotic genes. However, the G which is commonly found at the 3' end of the exons in most genes occurs infrequently in the pro  $\alpha$ 2 collagen gene. There appears to be a strong bias against the use of G in the third position of codons in this gene.

The introns defined by DNA sequence analysis range in size from 86 bp to more than 2,000 bp. The average G+C content of the introns is about 35%, in striking contrast to the G+C-rich (62%) coding sequences, resulting in an average G+C content of 40%. The structure of the pro  $\alpha 2$  collagen gene therefore consists of many small G+C-rich coding regions embedded in A+T-rich stretches of DNA.

There seems to be little homology between different introns. Computer-generated homology plots 17 show that the longest homologies are  $\sim 10$  bp. However, some of the introns seem to contain DNA sequences which are repeated in other parts of the genome. EcoRI fragments G, H and I all hybridize to a large size range of DNA fragments on Southern blots of chicken DNA (J.W., unpublished data). The observation that some of the introns contain sequences which are repeated in distal parts of the genome is similar to that found for the chick X gene, which lies near the ovalbumin gene 18, and the conalbumin gene 19, but contrasts with the structure of the ovalbumin and globin genes, where the introns contain only unique DNA 26.21.

### Number of exons

The DNA sequence determinations of various regions of the chicken pro  $\alpha$ 2 collagen gene indicate that the structure of this gene is complex. By integrating the data from the various techniques used to characterize this gene, we deduce the detailed picture of the gene's structure presented in Fig. 6. The placement and sizes of the exons, indicated by vertical bars in the figure, have been determined by DNA sequence analysis, Southern blot restriction mapping and electron microscopy studies of genomic DNA hybridized to procollagen mRNA in R-loop conditions. The parts of pro  $\alpha^2$  collagen for which individual exons code are detailed in Fig. 6 legend. Certain details differ from the arrangement of exons presented by Yamada et al.9 and Ohkubo et al.6, deduced from electron microscopy studies and limited DNA sequence analysis. The DNA sequence analysis of multiple exons coding for contiguous parts of the protein ensure that the number of exons in these regions and their placement with respect to the map presented in Fig. 6 are correct.

We have indicated in Fig. 6 that the pro  $\alpha$ 2 collagen gene contains 49 exons. This is only an approximate number, as some of the exons whose DNA sequences have not been determined are identified only by electron microscopy, in which small exons or introns may be undetected. However, the figure is a fairly accurate representation of the location and minimal number of exons. Note that the density of exons in the 3' half of the gene is higher than that in the 5' half; there is more than twice as much coding information in the last 19 kbp of the gene as in the first 19 kbp. From the 14 triple-helical coding exons whose sequences were determined, the average exon size is ~70 bp. This predicts a total of 41 to 42 exons for the triple-helical coding region (excluding the junction exons). Adding to this the four exons coding for the carboxy-terminal propeptide and several for the amino-terminal propeptide, we predict a total of about 50 exons in the pro  $\alpha$ 2 collagen gene.

The highly interrupted nature of the pro  $\alpha$ 2 collagen gene requires the transcription of 38 kbp of DNA and the precise removal of about 50 introns to produce a single mature 5-kbp messenger RNA. The large number of splicing reactions which must take place certainly suggests that RNA splicing is in some sense processive, that is, that the enzyme would start at an intron/exon junction and search processively down the intron DNA for a complementary splice point<sup>22</sup>. An alternative random mechanism would probably result in the excision of one or more coding regions, producing an error frequency intolerable for a gene with 50 exons.

Regardless of whether the introns arose concurrently with the evolution of the gene or were inserted after the gene was developed, it seems clear that there must be a reason for maintenance for this highly interrupted structure. It is possible that the introns help to stabilize the coding sequences. Investigation of the silk fibroin gene, which also has highly internally repetitious coding sequences but only one intron in the entire gene, has shown that different alleles of the gene give rise to differently sized fibroin molecules<sup>23</sup>. The size differences appear to result from changes in the size of the repetitive parts of the genes, presumably a result of recombination between these parts in misaligned genes, that is, homologous unequal crossingover. By embedding the repetitive collagen coding sequences in nonhomologous DNA (the introns), the probability of homologous recombination would be reduced<sup>24</sup>, thus stabilizing the size and structure of the collagen molecule.

#### Conclusion

The isolation of clones spanning 54 kbp of genomic DNA and DNA sequence determinations of over 4 kbp of this region, have shown that the chicken pro  $\alpha 2(I)$  collagen gene has a bizarre structure. The 5 kbp of coding sequences are spread out over about 38 kbp of genomic DNA, and are interrupted by some 50 introns. The exons coding for the amino- and carboxy-terminal ends of the triple-helical region also code for the telopeptides and part of the propeptides. The rapid accumulation of procollagen mRNA in embryonic connective tissue requires that the excision of the multiple noncoding regions in the primary transcript be both precise and efficient. Thus, we can now add a multistep assembly of coding regions in the nucleus to the multistep assembly of collagen chains (triple-helix formation, glycosylation, cleavage of propeptides, fibrillogenesis and crosslinking) in the cytoplasm and Golgi apparatus as a requirement for the production of collagen fibrils. One may wonder why the synthesis of this major component of the extracellular matrix has evolved into such an exquisitely complicated process.

We thank J. Slightom and D. Engel for providing their Charon 4A chicken DNA libraries, T. McDonnell for electron microscopy studies of mRNA-DNA hybrids, A. Courey for analysis of probes used to obtain some of the genome clones and Liz Levine for technical assistance. This research was supported by grants from the NIH and Muscular Dystrophy Association.

### The 26.13 MHz absorption line in the direction of Cassiopeia A

#### A. A. Konovalenko & L. G. Sodin

Division of Radio Astronomy at the Institute of Radiophysics and Electronics, Ukrainian Academy of Sciences, Kharkov, USSR

It has recently been suggested that the absorption line  $\nu =$ 26.13 MHz that we had detected<sup>2</sup> in the direction of Cassiopeia A might be a recombination line due either to carbon (C631 $\alpha$ ) present in H I clouds or to heavier elements of hot gas. Observations reported here taken in February 1981 suggest that the low-frequency attenuation in the spectrum of Cas A is due to the presence of a cold cloud of ionized carbon.

Recombination lines can be defined by measuring adjacent lines, for example  $630\alpha$  and  $632\alpha$  in the present case. We carried out similar observations during the summer of 1978 although these were hampered by high interference. We have re-examined a series of the spectra near the line C630 $\alpha$  ( $\nu$  = 26.250 MHz) and averaged the maximum number of recordings not deteriorated by interference (total time 3 h—see Fig. 1). The resulting spectrum contains an absorption line whose frequency  $(\bar{\nu} = 26.254 \text{ MHz})$  agrees well with the calculation for the  $C630\alpha$  at the local standard of rest and with allowances made

for the line-of-sight velocities in the Perseus arm. The intensity is close to that of the line  $\nu = 26.13$  MHz. Neither the H630 $\alpha$ nor the  $H631\alpha$  line are observed. In February 1981 we performed more observations. Figure 2 shows the spectrum near the frequency 25.04 MHz, showing the line  $C640\alpha$  in absorption.

Thus, it seems reasonable to assume that we have observed a recombination line of carbon. However, more measurements are planned during the summer of 1981 (the most favourable time for observing Cas A) to check this assumption.

The decametric band spectral measurements were also carried out in other galactic directions, over a wide range of frequencies including both the <sup>14</sup>N lines and  $Hn\alpha$ ,  $Hen\alpha$  and  $Cn\alpha$  recombination lines which were not detected. The upper estimate of their intensities was  $\Delta T_{\rm L}/T_{\rm c} < 3 \times 10^{-4}$  (ref. 3).

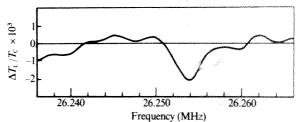

Fig. 1 The spectrum near the line C630a. The frequency corrected for motion of the Earth. Frequency resolution, 4 kHz; storage time, 3 h.

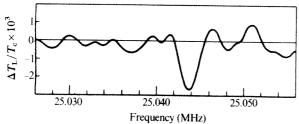

Fig. 2 The spectrum near the line  $C640\alpha$ . The frequency corrected for motion of the Earth. Frequency resolution, 2 kHz; storage time, 10 h.

If the observed absorption line were really due to ionized carbon, it would yield unexpected results.

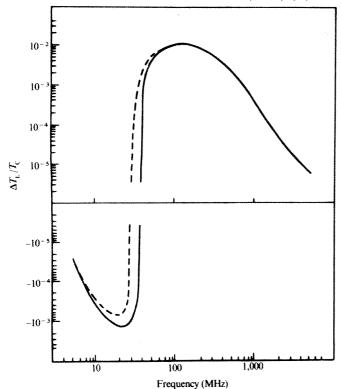

The frequency dependence of the carbon line intensity in the direction of Cas is interesting. Considering only frequencies  $\nu < 1,000 \, \mathrm{MHz}$  where the brightness temperature of Cas A is essentially higher than the electron temperature of the cloud, we have for the relative intensity of the recombination line4

$$\frac{\Delta T_{\rm L}}{T_{\rm c}} = -\tau_{\rm L}^* \left[ 1 - \frac{kT_{\rm e}}{h\nu} \left( 1 - \frac{B_n}{B_{n+1}} \right) \right] e^{-\tau_{\rm c}} B_n$$

where  $\tau_L^*$  is the equilibrium optical depth at the recombination line;  $\tau_c$  the optical depth in the continuum; and  $B_n$  a factor accounting for the deviation of the nth level from the local thermodynamic equilibrium conditions.

Figure 3 illustrates the relative intensity of carbon recombination lines as a function of frequency for  $N_e = 0.1 \text{ cm}^ T_e = 50 \text{ K}$  and measure of emission,  $ME = 0.07 \text{ cm}^{-6} \text{ pc}$ . The values of  $\Delta B_n/B_n$  for n > 500 are an extrapolation of earlier data<sup>5</sup>:  $\Delta B_n/B_n = 7 \times 10^{-6}$  at 25 MHz (solid line) and  $\Delta B_n/B_n = 10^{-6}$ 2×10<sup>-5</sup> at 25 MHz (dashed line).

Figure 3 shows that the lines observable in the decametre waveband are absorption lines; at 26 MHz the results which fit our measurements  $(\Delta T_{\rm L}/T_{\rm c} \sim 2 \times 10^{-3})$  are similar to those reported by Blake et al. Near 40 MHz the lines are extremely weak. They can be observed as emission lines at frequencies  $\sim$ 150 MHz, reaching quite high intensities (to  $10^{-2}$ ). This is also true for recombination lines of hydrogen with the same parameters as above. However, because the latter have never been detected either in the direction of Cas A (refs 3, 6, 7) or in

The calculated relative intensities of carbon recombination lines versus frequency

other directions, it suggests a low degree of ionization of the hydrogen clouds  $\zeta_H < 10^{-17} 1/c$ . The band of analysis used in the search for the  $H300\alpha$  (ref. 6) and  $H352\alpha$  lines (ref. 7) covered some carbon lines. The present calculations show the detectability of such lines for carbon clouds compared with the parameters given by Blake et al.1. In the spectrum of Shaver et al.<sup>7</sup>, several values have been excluded near the C352 $\alpha$  line ( $\nu = 150.214$  MHz), as allegedly deteriorated by interference. If the theoretical data given by Shaver<sup>4,5</sup> are correct, the carbon line should be observed in emission, with an intensity almost one order of magnitude higher than the detection threshold achieved. In this regard, observations in the frequency range 100-200 MHz would be of interest where emission recombination lines can be detected in cold clouds if they are sufficiently amplified by induced radiation.

Until recently, the decrease in the intensity of low-frequency radiation from Cas A was explained by the presence on the line of the sight of a H II region, with the electron concentration  $N_e \sim 1 \text{ cm}^{-3}$ , temperature  $T_e \sim 5,000 \text{ K}$  and  $ME \sim 100 \text{ pc cm}^{-3}$ (refs 7, 8). However, almost the same amount of free-free absorption can be caused in this direction by a cloud of carbon with  $N_e = 0.1 \text{ cm}^{-3}$ ,  $T_e = 50 \text{ K}$  and  $ME = 0.07 \text{ pc cm}^{-6}$ . Hence, the low-frequency attenuation in the spectrum of Cas A might well be due to the presence of a cold cloud of ionized carbon.

### High-sensitivity detection of negative ions in the stratosphere

### J. L. McCrumb & F. Arnold

Max-Planck-Institut für Kernphysik, 6900 Heidelberg, PO Box 103980, FRG

Mass spectrometer composition measurements of stratospheric negative ions were first made by Arnold and Henschen<sup>1</sup> using a balloon-borne instrument. These initial measurements, which were taken at an altitude of 36.5 km, revealed that the major ion species are  $NO_3^-(HNO_3)_a$  and  $HSO_4^-(H_2SO_4)_b(HNO_3)_c$ . The suggestion that the unexpected HSO4 cores are formed from NO<sub>3</sub> cores by a reaction involving stratospheric sulphuric acid vapour was strongly supported by laboratory measurements of the relevant ion-molecule reactions by Viggiano and colleagues2. Meanwhile, major instrumental refinements in balloon-borne ion mass spectrometers, including increased mass range, sensitivity and mass resolution, have resulted in the detection of more massive HSO4(H2SO4), ions and in the extension of the height range from a thin layer around 35 km to a region extending from 23 to 39 km (refs 3, 4). Here we report in situ negative ion composition measurements of even higher sensitivity which led to the detection of previously unobserved ion species.

The instrument, which has been described in detail elsewhere<sup>3,5-7</sup>, consists of a cryogenically (liquid neon) pumped quadrupole mass filter with single ion detection by a channel electron multiplier operating in a pulse-saturated ion counting mode. The ions were drawn into the pumped chamber by applying 10 V to the front plate. The mass filter, which has a mass range of 0-276 AMU, can be operated in various modes differing in mass resolution and sensitivity. It also includes a so-called integral mode which allows the detection of ions having masses >276 AMU (see ref. 3). The ion detection limit of the present instrument is about 1 ion cm<sup>-3</sup>, which corresponds

to a fractional ion abundance of  $5 \times 10^{-4}$  at 34 km. This 20-fold improvement in sensitivity over previous instruments was obtained by a simplification of the ion optical system—an enhanced ion signal was obtained by removing ion lenses and focusing elements between the inlet orifice and the quadrupole. An additional increase in counting efficiency was achieved by placing a grid directly in front of and at equipotential with the detector channel multiplier.

The present measurements were taken on 26 September 1980 during a daytime flight over southwestern France. Figure 1 shows data obtained at the peak or 'float' altitude of 34 km at noon local time. The US Standard Atmosphere temperature for this location and time is 234 K (ref. 8). An additional measure of temperature was obtained by considering the proton hydrate positive ion spectrum taken during the same flight'. Taking the measured ratio of adjacent proton hydrates, H<sup>+</sup>(H<sub>2</sub>O)<sub>3</sub>/H<sup>+</sup>(H<sub>2</sub>O)<sub>4</sub>, a typical water mixing ratio of 4 p.p.m. and the laboratory thermodynamic data of Kebarle<sup>10</sup>, we calculate a temperature of 237 K at 34 km. As the US Standard Atmosphere temperature represents average stratospheric conditions and because our method for temperature determination has not been independently corroborated, we assume an average of 235 K with error bars of 5 K.

Two sample spectra are shown in Fig. 1. The spectrum of highest resolution or A-mode spectrum (Fig. 1a) and the expanded version (Fig. 1b) is the sum of 100 mass sweeps of 11 s each; the peak width at half height is  $\sim$ 4 AMU. The spectrum shown in Fig. 1c is the sum of 50 sweeps with the mass spectrometer in the B-mode; in this mode a larger ion sensitivity

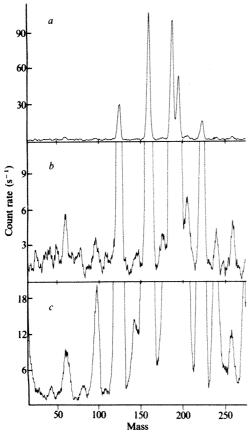

Fig. 1 Sample negative ion spectra measured at 34 km. The total scan time was 1,100 s and the dark count rate was 1 c.p.s. a shows major ions with the mass spectrometer set at its highest resolution (A-mode); b is the some A-mode spectrum expanded to show minor peaks; c was taken with mass spectrometer set for lower resolution but higher sensitivity (B-mode). The large apparent peak at the lower end of the B-mode scale is due to the integral signal at zero mass of the quadrupole<sup>3</sup>. Counting statistics were improved by subjecting raw data, divided into 1,000 channels along the mass scale, to a running mean averaging where the 'window' was smaller than the peak width.

Table 1 Mass numbers, ion identifications and fractional ion count rates of negative ions at 34 km

Mass (AMU)	Ion	Fractional ion count rate (%)
	Group I

Ions are separated into groups according to peak count rates. Adjustment in the fractional ion count rate was made for sulphuric acid clusters which are out of mass range of the instrument (see ref. 3).

is obtained at the expense of mass resolution (the peak width is  $\sim$ 7 AMU). The A-mode allows an unambiguous mass identification for the major peaks ( $\pm 0.5$  AMU). For the peaks near the detection limit the total signal is of the order of 100 ion counts per AMU; the dark current is about 20 counts per AMU interval (A-mode). Thus, poor counting statistics and associated poor peak shape result in a mass uncertainty of  $\pm 2$  AMU.

It can be seen that in the low mass region of Fig. 1 peak crowding and poor counting statistics hamper peak identification in the A-mode; in the B-mode, although the peak widths are larger, the minor peaks are more readily identified. In the high mass region, on the other hand, the A-mode spectrum is more informative. This is due to extended flanks of the dominant acid peaks in the B-mode spectrum which in many cases overlap and mask the much less intense minor peaks. Another feature evident in Fig. 1 is the change in abundance of some of the minor peaks between the A- and B-modes, notably the relative abundances of mass  $61\pm1$  to  $97\pm1$  AMU and mass  $240\pm2$  to  $259\pm2$  AMU. Although this difference may result partly from statistical fluctuations in the least sensitive A-mode, it could also be due to temporal and/or spatial variations in the ambient ion composition.

Table 1 is a compilation of observed mass peaks identified from spectra like those in Fig. 1 together with tentative ion assignments. Comparison of the integral mode and the resolving mode spectra reveals that most of the ambient ions have masses >276 AMU and thus could not be analysed. This result is consistent with other recent in situ observations<sup>3,4</sup>

To aid discussion, the ions listed in Table 1 have been separated into three groups according to ion signal strength. Group I consists of ions with fractional ion count rates >0.01 and whose mass numbers can be identified to within  $\pm 0.5$  AMU. These ions belong to the families  $NO_3^-(HNO_3)_a$  and  $HSO_4^-(H_2SO_4)_b(HNO_3)_c$  and have all been observed previously with fractional ion count rates similar to those reported here  $^{1.3.4}$ . The minor ions fall into two groups: those with fractional ion count rates between 0.001 and 0.004 are placed in group II and

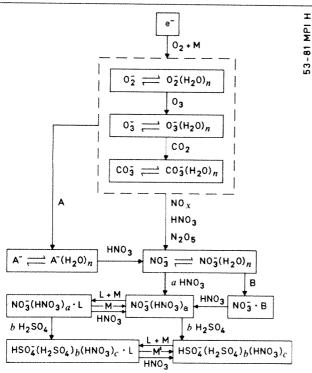

Fig. 2 Stratospheric negative ion reaction scheme including proposed minor ion species. L refers to the ligands H<sub>2</sub>O, HCl and HOCl. Hydrate equilibria are established quickly due to the relatively high water concentrations.

those with count rates between 0.005 and 0.001 in group III. In general, the peaks in group III are the most poorly defined and contain the largest uncertainty; nevertheless, their count rates are significantly above the background signal. The relatively higher count rates and better peak shapes of group II ions allow a mass number determination of  $\pm 1\,\mathrm{AMU}$  compared with  $\pm 2\,\mathrm{AMU}$  for the group III ions. In some cases, such as with  $174\pm 2\,\mathrm{AMU}$ , the mass position cannot be accurately determined because of the presence of an adjacent major peak.

As with the major negative ions, the minor ions seem to contain  $NO_3^-$  and  $HSO_4^-$  cores. There are, however, at least two cases where this does not apply; the core ion for the masses 26 and 43 is tentatively identified as  $CN^-$ . Also, due to the limited accuracy in mass number identification, we cannot exclude a contribution from  $CO_3^-$  and  $CO_3^ CO_3^-$  H<sub>2</sub>O to the peaks at  $CO_3^-$  and  $CO_3^-$  H<sub>2</sub>O to the peaks at  $CO_3^-$  and  $CO_3^-$  other than HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub>. These ligands are tentatively identified as H<sub>2</sub>O, HCl, HNO<sub>2</sub> and HOCl. Although certainly not unique, these identifications seem reasonable; such Brönsted-Lowry acids are known to bond strongly to negative ions 11. H<sub>2</sub>O, the weakest of the acids, is also a likely ligand due to its large abundance. Arijs et al. 4 have also recently reported several minor ions containing H<sub>2</sub>O ligands.

As a certain ambiguity exists in the assignment of cluster ions on the basis of mass alone, we have also used physicochemical arguments to obtain ion identifications. We expect water as a second or third ligand, for example, only if the precursor cluster ion has a relatively high abundance. This is due to the relatively weak  $H_2O$  ligand bonds and to the general decrease in free energy of bonding with increasing ligand number 12. Thus, the ion at  $142 \pm 2$  AMU could well be  $NO_3^-HNO_3^-H_2O$  or the ion at  $206 \pm 2$  AMU  $NO_3^-(HNO_3)_2 \cdot H_2O$ ; the precursor clusters in these cases,  $NO_3^-\cdot NHO_3$  and  $NO_3^-(HNO_3)_2$ , are major ions in the spectrum. On the other hand, the ion at 248 AMU is not given the structure  $HSO_4^-\cdot H_2SO_4\cdot HCl\cdot H_2O$  because of the low abundance of the  $HSO_4^-\cdot H_2SO_4\cdot HCl$  ion. The masses which cannot be decided on this basis are given in Table 1 with multiple cluster ion assignments.

The core ion CN should react with HNO3 via

$$CN^{-} + HNO_3 \rightarrow NO_3^{-} + HCN \tag{1}$$

as the electron affinity of CN  $(3.8\,\mathrm{eV})^{13}$  is smaller than that of NO<sub>3</sub>  $(4.0\,\mathrm{eV})^{14}$  and the bond energy of HCN exceeds that of HNO<sub>3</sub> (ref. 15). The absence of ions containing CN<sup>-</sup> cores with HNO<sub>3</sub> ligands also suggests that HNO<sub>3</sub> reacts with the core rather than attaches to it.

Proposed reaction schemes for stratospheric negative ions include the core ion CO<sub>3</sub>, but do not take CN<sup>-</sup> reactions into account<sup>16</sup>. Due to the large electron affinity of CN, the CN<sup>-</sup> core may be formed from O<sub>2</sub>, O<sub>3</sub> or CO<sub>3</sub> cores by reactions involving a CN compound, probably HCN. By assuming that CN<sup>-</sup> cores are lost primarily by a reaction involving HNO<sub>3</sub> and that their abundances reach a kinetic steady state, we estimate the HCN abundances as being of the same order as the HNO<sub>3</sub> abundance. This qualitative result is consistent with recent IR absorption measurements of Coffey et al.<sup>17</sup>.

Ions containing the ligands H<sub>2</sub>O, HCl, HNO<sub>2</sub> and HOCl would be expected to be lost by HNO<sub>3</sub> switching reactions because, for the cluster ion sizes considered, a ligand bonds more strongly the higher its gas phase acidity <sup>10</sup>. As the gas phase acidity of HNO<sub>3</sub> exceeds those of H<sub>2</sub>O, HCl, HNO<sub>2</sub> and HOCl (refs 15, 18), nitric acid should exoergically displace these ligands. It is also conceivable that ions containing such weakly bound ligands as H<sub>2</sub>O are lost primarily by thermal dissociation (see Fig. 1).

Fragmentation during ion sampling is known to be minimal for the strongly bound clusters with sulphuric and nitric acid ligands<sup>6,7</sup>; but an important question is whether the weakly bound H<sub>2</sub>O ligands are affected by fragmentation. This question might be answered by considering the hydration equilibria of the observed ions. However, for a hydration equilibrium to obtain. as opposed to a dynamic steady state, the dominant loss process for a hydrate ion A-H<sub>2</sub>O must be thermal dissociation and not switching with an ambient species of higher gas phase acidity. Using the forward rate constants and association free energies for several negative ion hydrations given by Fehsenfeld and Ferguson<sup>19</sup>, we calculate thermal dissociation rates which are typically an order of magnitude faster than nitric acid switching reactions calculated with an upper limit gas collision rate constant. Thus, if the hydrate ions are not significantly fragmented during ion sampling, the measured fractional abundances for A-H<sub>2</sub>O and A ions should reflect ion hydration equilibria of the form

$$\frac{[A^- \cdot H_2O]}{[A^-][H_2O]} = k_{eq} = \exp(-\Delta G/RT)$$

From the measured fractional ion count rates and a typical 4 p.p.m.v. water mixing ratio  $^{20}$ , we calculate the free energy differences,  $\Delta G$ , shown in Table 2. These values are compared with laboratory  $\Delta G$ s for the hydrations of  $CN^-$  and  $NO_3^-$ ; in the absence of data for the hydration of  $NO_3^-$ ·HNO $_3^-$  and  $NO_3^-$ (HNO $_3$ )<sub>2</sub>, we use available data for the hydration of  $NO_3^-$ ·H $_2O$  and  $NO_3^-$ (H $_2O$ )<sub>2</sub>. In view of the uncertainty in atmospheric parameters such as temperature and water concentration, the good agreement shown in Table 2 is fortuitous and no rigorous conclusions can be drawn from it; nevertheless, we feel that it provides further support for our ion

identifications as well as for the contention that the hydrates are not severely fragmented during ion sampling.

Ions containing the acid ligands HCl, HNO2 and HOCl may be formed either by three-body association or by switching of the corresponding ligand molecules. If association occurred at a gas collision rate and if HNO, switching was indeed the major sink for these ions, a steady-state treatment would yield an estimate for the abundances of HCl and HOCl of 0.1 to 1 times that of the HNO<sub>3</sub> concentration and for HNO<sub>2</sub> as roughly equal to HNO.

Although stratospheric IR absorption measurements show the HCl abundance to be comparable with that of HNO3 at 34 km (ref. 21), HOCl has not been observed. Calculations based on laboratory rate data of HOCl reactions and photolysis predict HOCl abundances which may be as large as that of HNO<sub>3</sub> (refs 22-24 and P. Crutzen, personal communication). We feel, therefore, that the identification of HCl and HOCl ligands attached to stratospheric negative ions is at least plausible.

Nitrous acid is another trace gas which has not been observed in the stratosphere. An important source of this species is the reaction NO+OH+M→HNO<sub>2</sub>+M and the main loss path is photolysis<sup>25</sup>. Photolysis of HNO<sub>2</sub>, however, is much more efficient than that of HNO<sub>3</sub> so that one would not expect the abundance of HNO2 to be as high as is apparent from the present measurements (P. Crutzen, personal communication). Clearly, further atmospheric as well as model investigations of this species are needed.

Finally, we note that HNO<sub>3</sub> concentrations may be derived from the present measurements by a method which relies on the existence of a kinetic steady state with respect to the nitric and sulphuric acid cluster ions taken as a whole. The common precursor of these clusters is the NO<sub>3</sub> hydrate family—seen here for the first time—and the common sink is ion—ion recombination. The steady-state continuity equation is simply solved for the HNO<sub>3</sub> concentration; it is

 $[NO_3^-(H_2O)_a]k[HNO_3] = [NO_3^-(HNO_3)_a$ 

 $+HSO_4^-(H_2SO_4)_b(HNO_3)_a]\alpha n_+$ 

where k represents the rate constants for HNO3 association and switching with  $NO_3^-(H_2O)_{\infty}$   $\alpha$  is the ion-ion recombination coefficient, and  $n_+$  is the total positive ion concentration. Taking  $k = 10^{-9}$  cm<sup>3</sup> s<sup>-1</sup> (Fehsenfeld *et al.*<sup>14</sup> report a lower limit of  $5 \times 10^{-10}$  cm<sup>3</sup> s<sup>-1</sup>),  $\alpha = 10^{-7}$  cm<sup>3</sup> s<sup>-1</sup> (refs 6, 7) and  $n_+ = 2,000$  cm<sup>-3</sup>, we obtain a HNO<sub>3</sub> concentration of  $7 \times 10^7$  cm<sup>-3</sup>. If, alternatively, the HNO<sub>3</sub> concentration is derived from the abundance ratio of NO<sub>3</sub>(HNO<sub>3</sub>)<sub>2</sub> and NO<sub>3</sub>·HNO<sub>3</sub> (equilibrium method, see ref. 26), one obtains values which depend strongly on the set of thermodynamic data used. The data of Davidson et  $al.^{27}$  ( $\Delta H = -18.3$  kcal mol<sup>-1</sup> and  $\Delta S = -22.1$  entropy unit) give  $7 \times 10^7$  cm<sup>-3</sup>, the data of Lee *et al.*<sup>27</sup> ( $\Delta H = -17.7$  kcal mol<sup>-1</sup>,  $\Delta S$ not measured, we calculate -20.1 e.u. from  $\Delta G$  values of Davidson et al.) give  $9.6 \times 10^7$  cm<sup>-3</sup>, and those of Wlodek et al.<sup>29</sup>  $(\Delta H = -16.3 \text{ kcal mol}^{-1}, \Delta S = -23.1 \text{ e.u.})$  give  $9 \times 10^9 \text{ cm}^{-3}$ . Comparison of the above inferred HNO<sub>3</sub> concentrations reveals agreement between the steady-state and equilibrium methods if the thermodynamic data of Davidson et al. are used. These values are also in reasonable agreement with recent model calculations of P. Crutzen (personal communication) which give an HNO<sub>3</sub> concentration of  $7 \times 10^8$  cm<sup>-3</sup> at 34 km. A word of caution is in order, however, concerning the degree of agreement in the above derived HNO3 concentrations. Considering the uncertainties in input parameters such as temperature and kinetic and thermodynamic data, this close agreement is certainly fortultous; it does, however, provide grounds for optimism about the use of ion measurements to deduce stratospheric nitric acid concentrations. Laboratory kinetic and thermodynamic studies of the relevant ions as well as improved in situ measurements are needed to improve our understanding of minor negative ions. Planned atmospheric measurements are aimed at an extended height range and an unambiguous mass identification of the minor ions.

Helpful discussions with E. E. Ferguson, P. Crutzen and D. Ehhalt are acknowledged. Part of this project was funded by the Bundesministerium für Forschung und Technologie through grant KBF 47.

### Near-edge X-ray absorption spectra for metallic Cu and Mn

G. N. Greaves, P. J. Durham, G. Diakun & P. Quinn

Science and Engineering Research Council, Daresbury Laboratory, Daresbury, Warrington WA4 4AD, UK

The measurement of X-ray absorption fine structure of metalsboth in the extended region (EXAFS) as well as in the near edge region (XANES)—has been widely discussed (see refs 1-6 for Cu and refs 7-9 for Mn). The recent availability of luteuse X-ray fluxes from storage rings has usually been exploited for EXAFS leaving the XANES often with poorer resolution than earlier work performed on conventional sources (for example, compare the near edge structure for copper in ref. 1 with refs 3 or 6). In addition, whilst the theory and analysis of EXAFS is relatively well-established. 1,18, a theory for the strong scattering regime near to the absorption edge has only recently been developed<sup>13</sup>. We report here the first high resolution XANES spectra for Ca and Mn which were performed at the SRS storage ring at Daresbury. Although both metals have close-packed structures consisting of atoms of similar size their local atomic structure is different in detail. Significant differences are found in their respective XANES reflecting the sensitivity of this region of the X-ray absorption fine structure to the local atomic structure. Spectra for the two metals have been analysed using the new multiple scattering formalism. This is a real space calculation and unlike a conventional band structure approach it does not require structural periodicity but works from the local arrangement of atoms.

K-edge absorption spectra for f.c.c. Cu (8.98 keV) and  $\alpha$ -Mn (6.54 keV) are presented in Fig. 1a, b with the respective

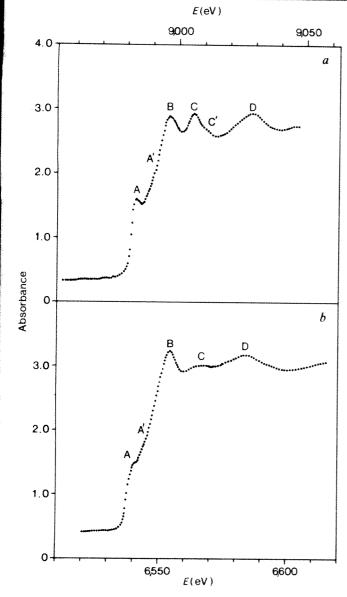

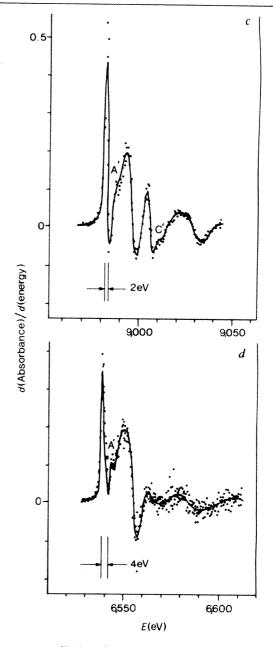

Fig. 1 XANES spectra for f.c.c. Cu (a) and α-Mn (b). Positions of peaks A, B, C and D are given in Table 1. Derivative XANES spectra for f.c.c. Cu (c) and α-Mn (d). Positions of A' and C' are given in Table 1. A cubic spline is included to guide the eye.

derivative spectra in Fig. 1c, d. The raw unsmoothed data are presented demonstrating the excellent signal-to-noise ratio obtained. Measurements were made at room temperature in transmission using 10-µm metallic foils supplied by Goodfellow Metals. The Cu foil was 99.99% pure and the Mn foil 98.7% pure (encapsulated in polyethylene). A Si 220 channel cut crystal diffracting vertically was used to monochromatize the white beam. Argon-filled ion chambers were used for detection in the conventional arrangement<sup>12</sup>. The 1-mm high entrance slits at 16 m from the source subtended an angle  $\Delta\theta$  of 13 arc s. This is two or three times larger than the angle subtended by the source or the width of the crystal rocking curve at these wavelengths and therefore defines the instrumental resolution. For the Si 220 crystal this is given by  $5.7 \times 10^{-5} \tan \theta \ \Delta \theta$  which for the Cu and Mn edges equals 1.5 and 0.8 eV respectively. ( $\theta$  is the Bragg angle given by  $\lambda = 3.84 \sin \theta$  Å). The 2-eV wide peak on the leading edge of the Cu spectrum (Fig. 1a) demonstrates the resolution achieved. The instrumental resolution was chosen to match the inherent spectral broadening. This derives from the finite lifetimes of the photoemitted electron and the core hole. Of these the core hole lifetime makes the principal contribution when the energy of the photoelectron is low. For Mn and Cu the inverse hole lifetime broadening is between 1 and 2 eV.

The spectra displayed in Fig. 1 were obtained during the commissioning period of the SRS when the machine was running with 10 mA of electron beam at an energy of 1.5 GeV. The comparatively low energy meant harmonic spectral contamination was minimized. However, coupled with the low beam current and the narrow entrance slits (1×10 mm), this reduced the photon flux at the sample  $^{13}$  to  $\sim 5 \times 10^7$  photons s<sup>-1</sup>. Data collection times resulted in typically 108 photons per point giving an integrated photon limited signal-to-noise ratio of 104. This value which compares well with the point-to-point noise recorded in the featureless parts of the spectra and indicates that there was no significant contribution from the detection system or from the residual scattered radiation in the vicinity of the ion chambers. For the SRS running at 2 GeV and 200 mA an improvement of at least an order of magnitude in signal-to-noise ratio is anticipated.

There are four strong peaks in the first 60 eV of fine structure for f.c.c. Cu. These are marked A, B, C and D in Fig. 1a, b. There is also some finer structure evident in the derivative spectrum (for example, A' and C' in Fig. 1c, d). The relative peak positions are listed in Table 1. Similar features also occur in the  $\alpha$ -Mn spectrum but the amplitudes are weaker on the whole (Fig. 1a, b) and the precise positions (Table 1) are different. This becomes clear by comparing the derivative spectra (Fig. 1c, d) where the similarity between f.c.c. Cu and  $\alpha$ -Mn only holds over the first

20 eV. The atomic volumes of copper and manganese are 11.7 and 12.1 Å<sup>3</sup> respectively and both have close-packed structures<sup>14</sup>. The differences in XANES almost certainly stem from the differences in local structure as other authors have concluded<sup>15</sup>. We will return to this point later.

Basically most fine structure in X-ray absorption spectra results from the scattering of the photo-emitted electron between the absorbing atom and those atoms surrounded it. The EXAFS at high energies (>50 eV above the absorption edge) is well described by single scattering theory10. In the XANES region close to the edge multiple scattering of the photoelectron plays an increasingly important part. As a result XANES in principle is sensitive to higher order atomic correlations<sup>11</sup> in addition to the pairwise correlations obtainable from EXAFS (or from X-ray or neutron diffraction, all of which are weak scattering probes). This means the fine structure is not simply interpretable as a combination of Fourier components—one for each shell of atoms9. Recently, Durham et al.11 extended the single scattering treatment of EXAFS4 to incorporate multiple scattering. In this approach the local density of states (the local electronic band structure 16,17) is built up by considering explicitly the relevant electron scattering paths within a finite portion of the system. Moreover in our theory the X-ray absorption cross-section is calculated in a real space representation, thereby removing the requirement, in band structure calculations, for relatively simple periodic structures.

Multiple scattering theory for XANES has been used successfully to predict the K-edge structure of f.c.c. Ag

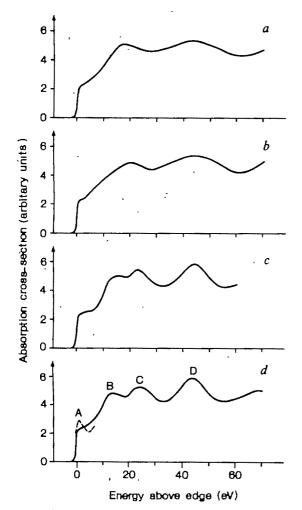

Fig. 2 Multiple scattering calculations for different cluster sizes of f.c.c. Cu; a, 1 shell; b, 2 shells; c, 3 shells; d, 4 shells. These consists of 12 atoms at 2.55 Å (1st shell), 6 atoms at 3.61 Å (2nd shell), 24 atoms at 4.42 Å (3rd shell) and 12 atoms at 5.09 Å (4th shell). The broken line in curve d represents the results of removing the broadening altogether in the vicinity of the edge.

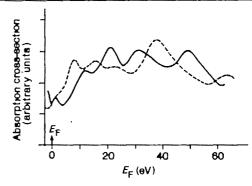

Fig. 3 Multiple scattering calculations for Mn in hypothetical b.c.c. (solid curve) and f.c.c. (dashed curve) structures, each with the same atomic volume as  $\alpha$ -Mn. Four shells of neighbour atoms are included in both calculations, and the Fermi level,  $E_{\rm F}$ , is an estimate consistent with band structure calculations  $^{20}$ .

(25.5 keV)11. The near edge structure of f.c.c. Cu shown in Fig. 1 is qualitatively similar to, but rather more pronounced than, that of Ag, and accordingly provides a more decisive test of the theory. Figure 2 shows a sequence of calculations for f.c.c. clusters starting with one shell and running up to four shells. Clearly the final calculation for a 55-atom cluster gives quite good agreement with experiment (Fig. 1). The four main peaks A, B, C and D are all predicted and their positions are accurate practically to within the experimental spectral resolution of  $\pm 1.5$  eV (Table 1). The relative amplitudes of the peaks as well as their individual asymmetries are also reproduced. Compared with experiment, however, the amplitude of the theoretical fine structure oscillations is approximately double what it should be. Whilst the calculated spectra have been broadened by 2.7 eV to match the inverse hole lifetime, no allowance has been made for the energy dependent inverse electron lifetimes, shakeup/shake-off effects or thermal disorder-all of which will decrease the amplitude of the fine structure oscillations. Our results are in good agreement with the APW band structure calculations of Wakoh and Kubo<sup>15</sup> (see Table 1). The rather similar K-edge spectrum of Ni has been investigated by Szmulowicz and Pease 18 using an APW calculation) who also discuss the origin of the main low-energy structures.

The XANES calculations for different sizes of cluster shown in Fig. 2 emphasize the sensitivity of this region to many shells of atoms. For instance, the four peaks of f.c.c. Cu are only reproduced when at least the third shell of 24 atoms at 4.42 Å is included. EXAFS is also sensitive to these outer shells, but this region of the absorption fine structure is dominated by the scattering effects of the first shell of 12 atoms at 2.55 Å (ref. 19).

The allotropes of Mn have extremely distorted structures of which  $\alpha$ -Mn is the usual form<sup>14</sup>. The overall packing density in  $\alpha$ -Mn is close to that in the b.c.c. structure but the local structure

Table 1 Peaks measured in the near edge structure of f.c.c. Cu and  $\alpha$ -Mn\* and the calculated positions for f.c.c. Cu using multiple scattering theory† with the APW band structure values‡

<sup>‡</sup> From Fig. 1 of ref. 15.

shows few similarities. In particular there are four distinct first coordination shells containing between 12 and 16 atoms. The calculated XANES for Mn in hypothetical b.c.c. and f.c.c. structures with the same atomic volume as  $\alpha$ -Mn is shown in Fig. 3. The obvious differences between the two calculations demonstrates their sensitivity to local structure. On the other hand the f.c.c. Mn calculation shows clear similarities with the f.c.c. Cu calculations, but contains slightly more structure. In the same way the b.c.c. Mn calculation is qualitatively similar to the calculations of Wakoh and Kubo<sup>15</sup> on b.c.c. V and Fe. Comparison with experiment in Fig. 1 shows, however, that neither the b.c.c. nor f.c.c. Mn calculations agree well with the spectrum of  $\alpha$ -Mn. Although there are experimental similarities

between a-Mn and Cu XANES, the amplitude of the oscillations are smaller for  $\alpha$ -Mn; for instance, peak A in the Cu spectrum becomes a shoulder for Mn. Evidently the quasidisordered nature of the local structure in  $\alpha$ -Mn tends to wash out the sharp features of a more symmetrical structure. Preliminary multiple scattering calculations for the first shell of  $\alpha$ -Mn display a significant variation in the fine structure for different inequivalent sites, the amplitude of which diminishes when an average is taken. More detailed calculations will be published later.

### Solid-state reduction of iron in olivine -planetary and meteoritic evolution

### J. N. Boland & A. Duba\*

State University of Utrecht, Institute of Earth Sciences, Budapestlaan 4, PO Box 80.021, 3508 TA Utrecht, The Netherlands

Iron-nickel metallic particles have been reported in meteorites<sup>1</sup> and lunar<sup>2-5</sup> and terrestrial<sup>6,7</sup> rocks. The origin of these metallic particles is not unique as they may be formed by (1) condensation from a primordial solar nebula<sup>8</sup>; (2) crystallization from a melt; and (3) subsolidus reduction reactions under low oxygen or sulphur fugacity. We report here an electron microscopy study of the solid-state microstructural development in olivine single crystals (Fo<sub>92</sub>) in which half of the iron has been reduced to the metallic state by a gas-solid interaction in the temperature range 950–1,500 °C. The reaction,  $Fo_{92} \rightarrow Fo_{96} + metallic Fe(Ni$ in solid solution) + pyroxene, begins with a homogeneous transformation involving fine-scale metallic precipitates resembling Guinier-Preston zones'. The microstructure develops by the growth of the first-formed precipitates during an Ostwald ripening process9 in which the precipitates located in the dislocation sub-boundaries develop in preference to precipitates in the subgrains. On the other hand, pyroxene is first observed to nucleate heterogeneously at pre-existing dislocations and its coarsening rate is more than an order-of-magnitude faster than that of the metallic phase. Besides the textural similarity of the observed microstructures with that reported for some of the lunar materials2, these results have important implications for the physical models of accretion of terrestrial planets, planetesimals and meteorites<sup>10</sup>, especially with respect to the distribution of siderophile elements. The rate of reaction observed here places constraints on models for the formation of the Earth's core by segregation of a metallic phase with or without reduction.

Single crystals of San Carlos olivine, Fo92, were heated under controlled oxygen fugacity,  $f_{O_2}$ , to temperatures in the range 950-1,500 °C and the conductivity of the samples measured These results indicated that the time-dependent variation in electrical conductivity was associated with a change in the

oxidation state of iron. One sample (B) that had experienced reducing conditions during conductivity measurements was selected for electron microscopy studies. In addition, sample A was heated in the experimental assembly without conductivity measurements to study the early stages of the reduction reaction—it spent 1 h at 1,400 °C, 3 h at 1,300 °C and 1 h at 1,200 °C in CO/CO2 mixtures defined by line A in Fig. 1. Sample B was at 1,500 °C for 1.5 h, 1,400 °C for 2 h and 1,300 °C for 21 h in H<sub>2</sub>/CO<sub>2</sub> mixtures defined by region B (Fig. 1). The conductivity of sample B decreased by 50% in the first 2 h but remained unaltered during the next 23 h.

Assuming that the conductivity decrease is due to Fe loss from the olivine 11, then the reaction of olivine with the imposed  $f_{O_2}$  is completed within the first 2 h at these temperatures. Consequently, sample A should represent the earliest stages in the nucleation and growth of the metallic phase produced by the reduction reaction, while sample B would indicate the microstructural development in the coarsening process. To determine the growth rate parameters, all kinetic data were standardized to 1,300 °C. After the reaction, the composition of the matrix in sample B was Fo<sub>96</sub>, while its initial nickel content of 0.33 wt% was reduced to a level that was undetectable. Because of the homogeneous distribution of the fine-scaled precipitates in sample A, it was not possible to determine the matrix composition.

The microstructure of sample A was variable. The first indications of the reduction process were the matrix strain-field contrast effects<sup>12</sup> shown in Fig. 2a. These effects were homogeneously distributed in this region of the sample and not markedly affected by the pre-existing dislocations. However, in other areas, the dislocations had precipitates attached to them (Fig. 2b). Using the energy dispersive system attached to the JEOL 200 C microscope, the precipitate was analysed as a pyroxene. Unfortunately no extra diffraction information was found in the fine beam (0.05 µm) microdiffraction pattern. Sample B contained 0.2-1.5 µm blebs of iron-nickel (2 wt% Ni) distributed predominantly in dislocation sub-boundaries. These precipitates (M), kamacite, (identified by selected area electron diffraction), were located in the edge-dislocation sub-boundaries composed of b = [100] and b = [001] dislocations but were absent from cross-arrays of screw dislocations (Fig. 3a). Scanning electron microscopy indicated that the coarsening process for the metallic phase occurred throughout the bulk of the sample (Fig. 3b) and high-voltage microscopy (0.9 MeV) confirmed the distribution of the phase in thick sections (4-

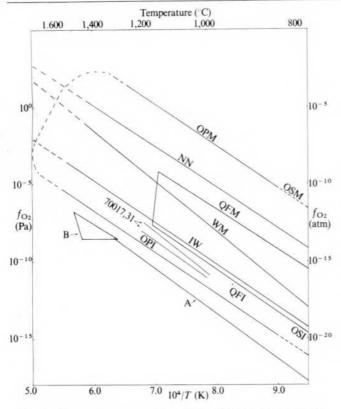

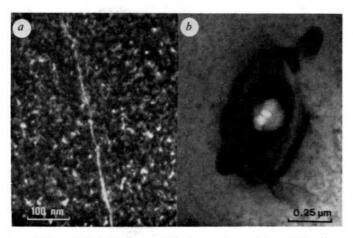

Fig. 1 Temperature versus  $f_{\rm O2}$  stability of olivine (after ref. 37) with 10% fayalite and pure fayalite, respectively compared with various oxygen buffers and lunar samples. OPM (olivine, pyroxene, magnetite) and OSM (olivine, silica, magnetite) delineate the oxidation of olivine with 10% fayalite. Reduction of olivine of that composition is indicated by OPI (olivine, pyroxene, iron) and OSI (olivine, silica, iron). For fayalite, the oxidation boundary is indicated by QFM (quartz, fayalite, magnetite) and QFI (quartz, fayalite, iron) (see ref. 34 for detailed discussion of these stability fields). The buffers NN (nickel-nickel oxide), WM (wisite-magnetite), and IW (iron-wüstite) are shown for comparison. Also shown is the intrinsic  $f_{\rm O2}$  determined for lunar basalt  $^{35}$  and the experimental paths A and B discussed in the text.

 $5 \mu m$ ). However, the pyroxene that formed during the reduction reaction was more heterogeneously distributed than in sample A, and, when observed, had grown to precipitates larger than  $5 \mu m$ . It had a high density of planar faults lying in the (100) planes that produced streaks in the diffraction pattern; there were also clinoenstatite lamellae up to  $0.1 \mu m$  wide in the orthopyroxene<sup>13</sup>. Although the starting material had a dis-

**Fig. 2** a, A dark-field image of the fine-scale precipitates of Fe-Ni in the olivine matrix—the dislocation has not acted as a preferred nucleation site: sample A. b, A pyroxene precipitate located at a dislocation loop: sample A.

location density of  $4(\pm 2) \times 10^5$  cm<sup>-2</sup> with widely spaced (100) and (001) dislocation sub-boundaries ranging from 50 to 100  $\mu$ m, sample B had an average subgrain size of 2.5  $\mu$ m and a free dislocation density of  $6(\pm 3) \times 10^8$  cm<sup>-2</sup>.

Figure 4 illustrates what is postulated to be the coarsening process for the metallic phase. The precipitate  $(M_1)$  within the subgrain is dissolving while the precipitate  $(M_2)$  at the subboundary coarsens. The dissolution reaction at  $M_1$  involves predominantly lattice diffusion with some minor pipe diffusion along the attached dislocation while the growth process of  $M_2$  occurs by pipe diffusion down the dislocation in the sub-boundary. This is the most likely mechanism for the growth of the few larger iron-nickel particles observed in the SEM (Fig. 3b).

It is apparent that the nucleation and growth processes of the metallic and silicate phases are different. The earliest evidence of the pyroxene is at pre-existing dislocations while the matrix still shows the strain-contrast effects, assumed to be the iron-nickel pre-precipitates, similar to Guinier-Preston (GP) zones<sup>9</sup>. However, incoherency at the interphase boundaries soon develops <sup>14,15</sup> producing both interfacial and lattice dislocations.

The growth rate of the pyroxene is difficult to estimate but the coarsening rate of the metallic phase can be calculated from the conductivity measurements on sample B, using a diffusion-controlled model for precipitate growth 16 and Fe diffusivity in olivine 17. The effects of pressure are important for reactions that may occur in the mantle. Pressure influences the diffusivity of Fe through the PV term in the general diffusion equation 18, where V is the activation volume for the rate-controlling step. One experimentally-determined value of V in olivine, based on the dislocation recovery rate, is 11 cm3 (ref. 19). This dislocation climb-related process is probably controlled by oxygen diffusivity. In another study of the rheological behaviour of olivine in the upper mantle, a value of 7 cm3 was used, assuming that both power-law creep and diffusional flow were controlled by oxygen ion diffusivity  $^{18}$ . There are no reported values of Vfor Fe diffusion in olivine, so a range of values-0, 1, 7 and 11 cm3-has been used to calculate precipitate sizes. Pressure and temperature influence the stability of olivine. To depths of 400 km (150 kbar), olivine is stable but with increasing depth, it transforms according to the following<sup>20</sup>: at 400 km olivine transforms to the β-polymorph; in the range 400-650 km the  $\beta$ -phase will transform to the spinel phase,  $\gamma$ ; at  $\sim$ 650 km the spinel most likely transforms, by a disproportionation reaction, into the perovskite and rocksalt structures which seem to persist deep into the lower mantle.

The temperature of the olivine to  $\beta$ -phase transformation is estimated to be 1,650 °C, based on the mantle temperature distribution <sup>10</sup>. Taking these P, T conditions to be the optimum

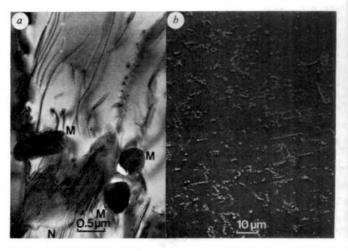

Fig. 3 Iron-nickel precipitates (M) in sample B. a, The precipitates are located in the edge dislocation sub-boundaries but they are absent from the cross-array of screw dislocations at N. b, SEM showing the clustering of the metallic precipitate as well as the crystallographic alignment: sample B.

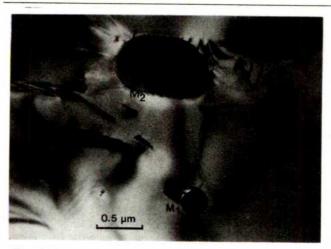

Fig. 4 The smaller metallic precipitate at  $M_1$  lies within the subgrain while the larger precipitate,  $M_2$ , is attached to the (100) edge dislocation sub-boundary-according to the postulated coarsening mechanism,  $M_1$  is dissoving while  $M_2$  is growing: sample B.

for the growth of the iron (nickel) precipitates in olivine the precipitate sizes expected after 10° yr coarsening are 20, 15, 2 and 1 mm using the values of V given above. These calculations, based on our experimental results, use the Gibbs-Thompson equation 14,16 assuming: (1) the precipitate/matrix interfacial free-energy and, (2) the equilibrium solubility of Fe in the matrix (for large precipitates), are constant over the P-T ranges used. Although there are no data for the Fe diffusivity in the  $\beta$ ,  $\gamma$ , perovskite and rocksalt structures, it is unlikely that the coarsening rates will differ by more than one or two orders of magnitude from the values calculated according to the olivine data, provided appropriate P, V and T values are used in the diffusion equation. For example, based on the olivine data, in 109 yr, at 2,000 km (corresponding to 2,500 °C and 100GPa-1 Mbar), the precipitate size would be about 5 mm for a V of 1 cm<sup>3</sup>. One other variable is the  $f_{O_2}$ . Intrinsic  $f_{O_2}$  measurements21 on spinels from peridotites indicate a wide range from just above the iron-wustite buffer to the OPI buffer (Fig. 1). for will certainly influence the diffusion coefficient but as with Ni diffusion in NiO (ref. 22) the effects may be small for very low foz.

Although solid-state diffusion may not lead to any large particles of iron-nickel, it has recently been proposed that the incorporation of Fe (and Ni) in refractory metal particles in the Allende meteorite occurs as a postnebular condensation-reduction reaction<sup>23</sup>. In addition, the condensates from a nebular gas accrete to form planetesimals and ultimately the planets. Unless the accreting body is completely molten, it will be necessary to transfer iron (and nickel) from a solid silicate phase into the metallic phase which may be molten (see below); in addition, other light elements including sulphur, oxygen, silicon and hydrogen may diffuse into the metallic phase. The mechanism of formation (nucleation) and coalescence (coarsening) of the metal will be critical steps in the segregation/ sinking stage of the metallic phase into the formation of the core, regardless of whether the overall accretional processes are described as homogeneous<sup>10</sup> or heterogeneous<sup>24,25</sup>.

For a homogeneous transformation involving GP-like zone formation, the diffusivity pathways are exceedingly small, possibly no greater than 200 Å between zones. However, if the zones are now liquid instead of solid, the coarsening process would not involve the slow solid-state, Ostwald ripening process but a modified version of hydrodynamic dispersion in which the mass transfer occurs by molten iron convecting along subgrain and grain boundary channels. This mass transfer process has effective diffusivities several orders of magnitude greater than normal diffusivities26. In addition our observation shows that in the very early stages of the formation of metallic particles, nickel is preferentially removed from the silicate phase. To avoid the

excessive depletion of siderophile elements implied by such a process, advocates of the homogeneous accretional theory propose the sinking of large metallic 'drops' that originate close to the surface of the Earth<sup>27</sup> or at 1,500-2,000 km depths<sup>10</sup>. The former model implies that olivine would be the stable phase while in the later proposal the high-pressure polymorphs would be more appropriate. However, at such high pressures the ferrous ion in the silicate phase is expected to disproportionate into the ferric state plus metallic iron 28. In any case, whether the formation of a metallic phase is by a reduction reaction or disproportionation, a coarsening reaction is implied and our observations for the solid state and those relating to the molten state29, indicate that large-sized precipitates would not form. A further complication arises because there is no agreement as to the relative abundances of siderophile elements (contrast refs 10 and 30), leaving the metal-silicate partitioning a highly controversial issue in models of Earth and Moon formation.

The boundary conditions imposed by the coarsening rates of solid and/or liquid precipitates in a solid silicate phase indicate that the evolution of the mantle and core involves a multi-stage processing of primitive material. Relicts of these primitive microstructures would be rare<sup>31</sup> because of subsequent modifications occurring during phase transformations<sup>32</sup> and mantle convection33. Although the solid-state growth rates reported here are insignificant for the large scale phenomena needed for core formation, they are certainly adequate to account for the micrometre size metallic phases and exsolution lamellae reported in lunar rocks<sup>2,34,35</sup> and meteorites<sup>36</sup>.

We acknowledge the financial support of the Netherlands Organization for the Advancement of Pure Research (Z.W.O.) for all our electron microscopy including the high voltage microscopy at T.N.O. in Apeldoorn. Some conductivity measurements were made under the auspicies of the US Department of Energy, Basic Energy Sciences, by the Lawrence Livermore National Laboratory, contract no. W-7405-ENG-48. Further assistance was provided by a NATO research grant RG 112-81.

# Structural features in ethanol-water mixtures revealed by picosecond fluorescence anisotropy

### G. S. Beddard, T. Doust & J. Hudales

Davy Faraday Research Laboratory, The Royal Institution, 21 Albemarle St, London W1X 4BS, UK

When an ensemble of molecules is excited with polarized light an anisotropic orientational distribution with respect to the transition dipole moment is produced. This anisotropy can decay in time due to the rotational motion of the molecules and consequently leads to depolarization of the fluorescence 1-6. The rate of this rotational motion has been successfully predicted from hydrodynamic theory. How much the rotational relaxation depends on molecular geometry and how much on specific solvent-solute interactions has been studied by picosecond spectroscopy<sup>1-6</sup> and other techniques<sup>7-9</sup>. In all cases so far reported, the rotational behaviour seems to be accounted for by the Debye-Stokes-Einstein (DSE) equation  $\tau_R = f/kT$ . This relates the rotational relaxation time  $au_{
m R}$  (inversely related to the rotational diffusion coefficient) to the frictional coefficient, f, which is proportional to the product of the shear viscosity, the molecular volume and a constant dependent on the 'stick' or 'slip' boundary conditions<sup>3,10,11</sup>. We report here, however, that large deviations from DSE behaviour have been observed in the rotational diffusion of the dve cresyl violet in ethanol-water mixtures. Different rotational relaxation times are observed in solutions of the same viscosity but differing composition. This behaviour can be rationalized using previously proposed models for water-ethanol mixtures.

Most information previously obtained from fluorescence depolarization data has been concerned with solvent-solute interactions rather than with the solvent itself<sup>5,6</sup>. Figure 1 shows a plot of the rotational relaxation time of the dye cresyl violet (3,7-diamino-1,2-benzphenoxazine chloride) against relative solvent viscosity  $(\eta/\eta_0)$  for ethanol-water mixtures<sup>12</sup> (points 1-11 in order of increasing ethanol content) and for acetone, methanol and propan-1-ol (points 12-14 respectively). Also shown is the line calculated from DSE theory for cresyl violet at the 'stick' boundary condition. The molecular shape and volume were calculated from van der Waals' radii. The composition ions of the solutions are shown in the legend to

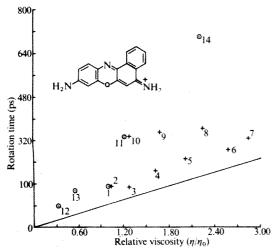

Fig. 1 Rotational relaxation time of cresyl violet (in ps) plotted against relative viscosity  $(\eta/\eta_0)$  for water-ethanol mixtures (points 1-11) with ethanol mole fractions of 0.0, 0.002, 0.024, 0.051, 0.079, 0.132, 0.207, 0.470, 0.706, 0.950 and 1.0. Acetone, methanol and propan-1-ol are points 12-14 respectively. The solid line has the slope calculated for DSE behaviour of cresyl violet at the 'stick' boundary condition.

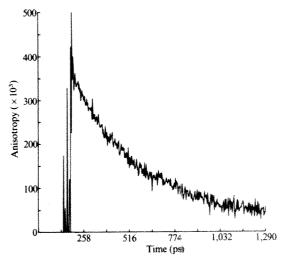

Fig. 2 The decay of the fluorescence anisotropy r(t) for cresyl violet at 770 nm in the 0.470 mole fraction ethanol solution, calculated from the fluorescence intensity parallel  $(I_{\parallel})$  and perpendicular  $(I_{\perp})$  to the excitation polarization using the formula  $r(t) = (I_{\parallel} - I_{\perp})/(I_{\parallel} + 2I_{\perp})$ . The anisotropy is related to the rotational relaxation time  $\tau_{\mathbf{R}}$  for a sphere by  $r(t) = r_0 \exp(-t/\tau_{\mathbf{R}})$ . For molecular shapes approximated to ellipsoids the formulae for r(t) given in refs 3 and 4 were used.

Fig. 1; all the experiments were carried out at 294K. The fluorescence of cresyl violet was measured with picosecond time resolution using a frequency up-conversion spectrometer<sup>6</sup>. The fluorescence anisotropy was calculated from the normalized fluorescence decays measured with polarization parallel and perpendicular to that of the exciting light. An example of the fluorescence anisotropy decay is shown in Fig. 2. The dye concentration was  $10^{-4}$  M in all the solutions and is low enough to avoid modification of the bulk properties of the solution.

The most noticeable feature of the rotational relaxation data are the dual values at identical solvent viscosities. We can identify two regions with which to explain the observations. First, in the high water region (points 1-7) DSE behaviour is observed and the gradient of the line of measured  $\tau_R$  against relative viscosity is the same as that predicted from the molecular volume. Second, after the maximum ethanol-water solution viscosity is reached (points 8-11) the rotational relaxation time decreases only slightly until the value for pure ethanol is reached, even though the relative viscosity changes by a factor of greater than 2. Ethanol-water mixtures show large positive deviations from Raoults law and the viscosity is a maximum at a mole fraction of 0.25 ethanol. We have observed similar behaviour in other alcohols which will be reported elsewhere.

The difference in rotation time of cresyl violet between pure water and ethanol has previously been explained by the specific interaction of ethanol with the amino groups on cresyl violet. This increases the effective volume of the molecule thus making molecular rotation slower. This argument, when extended to the other alcohols is the reason for their rotation times being well above the calculated 'stick' line, the solid line in Fig. 1. In water it seems that there is little interaction with the cresyl violet, presumably due to strong water-water interactions. In the related dye oxazine-1 (3,7-bis(N,N-diethylamino) phenoxazine perchlorate) the amino groups are ethylated, hence no interaction can occur at this site with the alcohols; consequently, the rotation times in alcohols and alcohol-water mixtures fall just below the line calculated for 'stick' limit behaviour 13.

Although the DSE theory was originally developed for large bodies moving in a continuum it seems, nevertheless, to be applicable to the description of small molecules moving in slightly smaller discrete solvents<sup>6,10</sup>. One reason for this would seem to be that the motion of the solvent is considerably faster than that of the dye molecules. For instance, a correlation time of 2.5 ps for the protons in water and 8 ps for the methyl protons in pure t-butanol has been reported<sup>14</sup>. The dye molecule, on the

other hand, rotates in  $\sim 150$  ps in pure water and 330 ps in pure ethanol. As the local environment around the molecule is changed many times during its rotational decay time the solvent effectively presents a continuum in which the solute moves. However, in the case of alcohol-water mixtures it seems that some structural features are maintained for long enough to affect the rotation of the solute.

Our results support models of 'hydrophobic hydration' deduced from thermodynamic and spectroscopic data 15-17. It is suggested that in the region of increasing viscosity, up to  $\sim 0.2$ mole fraction ethanol, the ethanol may be considered to lie in interstices in a three-dimensional water 'structure'. The hydrophobic part of the ethanol is surrounded by 'cages' of water although it does not interact significantly with these surrounding molecules<sup>14</sup>; the hydroxyl group, however, replaces one of the framework water molecules. The altered reorientational behaviour of the water molecules on adding ethanol is due to the enhancement of water-water interactions between these cages. The water-ethanol interactions play a smaller part<sup>18</sup>. At higher alcohol concentrations, above  $\sim 0.2$  mole fraction ethanol the ethanol can no longer be contained in the basic water structure and this disintegrates; breaking of the water-water hydrogen bonds leads to a decrease in viscosity. A more detailed and comprehensive discussion of the properties of water-alcohol mixtures is given elsewhere16

At low mole fraction of ethanol our results suggest (points 2-7, Fig. 1.) that the ethanol is surrounded by water as no specific interaction of the ethanol with the cresyl violet is observed; that is the variation of the rotational relaxation time with relative viscosity is that predicted for cresyl violet alone. Above the maximum viscosity when the ethanol is no longer contained in the water cages it is available for solvation of the cresyl violet. This is shown in the data by an increase in the measured rotational relaxation time when the solvent viscosity is decreasing (points 7-9). If the rotational diffusion rate at high ethanol concentrations were due to cresyl violet-ethanol interactions alone then  $\tau_R$  would be constant at 330 ps over the viscosity range.

The small variation in the rotation time over the viscosity range 2.8-1.2 indicates that in this composition range the cresyl violet is probing small pools of ethanol contained in the water. The slightly larger rotation times above 0.3 mole fraction (points 8 and 9) could be due to the small pool size at this composition as they are surrounded by water. This effect is analogous to that occurring for small pool sizes in reversed micelles where an increased viscosity is observed<sup>19</sup>. As the pools become larger the effect of the surrounding water is reduced and the rotation time tends towards that in pure ethanol. The possibility that the anisotropy decay probes free ethanol as well as water-ethanol cages was also considered. This would require the anisotropy to be a combination of two rotational decay times but analysis of the data in this manner will not support this supposition indicating that only a single species is present. Thus, due to its ability to interact preferentially with one component of the mixture cresyl violet can probe some of the structural features of alcohol-water mixtures that manifest themselves over a relatively long time, that is a few hundreds of picoseconds.

The Mid America Trench, off the Pacific coast of southern Mexico and central America, is the site of northeastward subduction of the Cocos oceanic plate under the North America and Caribbean plates1 (Fig. 1). In Guatemala, the North America and Caribbean plates are separated by the Polochic-Motagua left-lateral strike-slip faults (Fig. 1). The trench itself appears to be divided into two distinct sections at its intersection with the Tehuantepec Ridge. To the south the margin of the trench is wide and consists of a well developed shelf basin<sup>2</sup> bounded on the east by a huge volcanic cordillera parallel with the trench axis at a distance of ~200 km. In contrast, to the north, the margin is narrow and devoid of shelf basin; landwards, the trans-Mexican volcanic belt trends oblique to the trench. This volcanic chain would be anomalous if it were related to the subduction of the Cocos plate off southern Mexico. In 1979, as part of the International Phase of Ocean Drilling (IPOD) of the Deep Sea Drilling Project, Legs 66 and 67 respectively explored the northern (off Acapulco, Mexico) and southern (off San Jose, Guatemala) section of the Mid America Trench<sup>3-6</sup> (Fig. 1). Since then short topographical surveys of the trench have been carried out by RV Jean Charcot<sup>8</sup> using the sea-beam technique. We report here that both sets of data, together with UTMSI multichannel seismic profiles 10,11 can be used to reconstruct the processes of subduction along the Mid America Trench.

Leg 67 (refs 3, 4), in the southern section seems to include the first occasion that a drill-hole in an oceanic trench reached the oceanic basement. The sharp contrast between the Upper Cretaceous sequence at the base of the continental slope and the subducting Lower Miocene Cocos plate beneath it suggests that in the region of Leg 67, subduction is not accompanied by accretion. Data from Leg 66 (refs 4, 5) in the Northern section of the trench show an upslope increasing age of turbidites on the continental wall (Pleistocene up to Middle Miocene) indicating accretion. In the absence of more representative drilling data from the northern and southern sections, however, the results of Leg 67 could be explained by the slumping of a large block of Cretaceous material and those of Leg 66 by the trapping of coarse sediments in suspended ponded basins.

The results of the sea-beam surveys (Fig. 2a, b) confirm the general features of the Mid America Trench; they also give new data that clarify the mechanism of subduction in the northern and southern sections. The most striking feature of the data is that the Cocos plate is marked, in the neighbourhood of the trench, by elongated ponds and swells trending 130°-140° N, that are clearly oblique to the mean 110°-120° N direction of the trench (Fig. 2a, b). This horst and graben pattern, already known from previous seismic records  $^{10,11}$ , is thus not as parallel

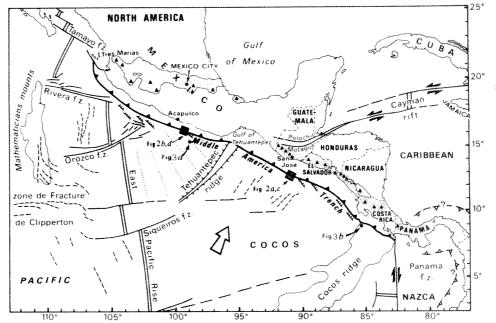

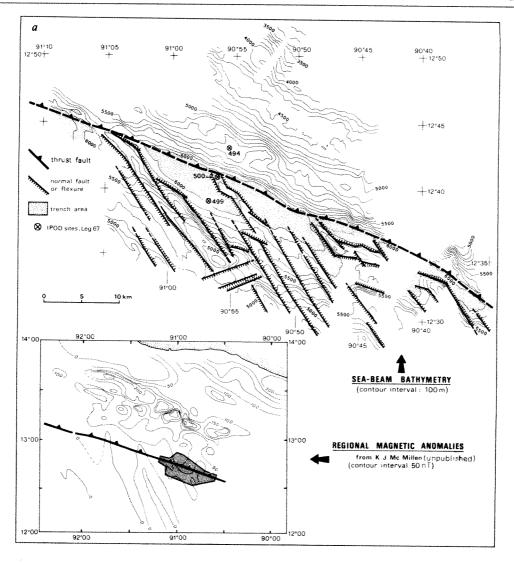

Fig. 1 Tectonic framework of the Mid America Trench.

to the trench axis as was assumed. In the Leg 66 area, at the mouth of the very active Ometepec canyon<sup>11</sup>, the Cocos pattern disappears towards the trench under a thick pile of turbidites (Figs 2b, d). In contrast, in the Leg 67 area, Cocos structures totally control the trench morphology. Indeed the trench consists of a succession of diamond shapes (corresponding to graben structures) and bottle-necks (corresponding to horsts) (Figs 2a, c). This is consistent with the drilling results at hole 500, just at the base of the continental slope, where a normal fault was suspected between Pleistocene trench sediments and Miocene chalk and where oceanic crust was reached 150 m above the same material in the trench<sup>3,4</sup>. Most probably hole 500 is just at the western edge of a Cocos horst. What about the origin of this oblique pattern? Is it an en échelon faulting due to oblique subduction or is it related to the Cocos plate internal grain? The latter solution is favoured by the clear parallelism observed between the horst and graben pattern and all known magnetic anomalies near the trench (refs 11, 12 and K. J. McMillen, unpublished data) (Fig. 2). Thus we consider that this structural pattern is controlled by inherited faults formed at the East Pacific Rise. Indeed it has been shown 13,14 that the genesis of oceanic crust along the East Pacific Rise is accompanied by dense normal faulting and fracturing, parallel with the spreading axis. These faults become inactive  $\sim 10 \text{ km}$  off the rise<sup>13,14</sup>; however, they still exist as mechanical discontinuities. The bending of the Cocos plate in the subduction zone induces surficial tensional stress that preferentially reactivates these older fractures. The easier the reactivation, the smaller the angle (20-30°) between the mean direction of the trench (110°-120° N) and that of inherited fractures (130°-140° N). Such a reactivation process has already been proposed—with far less evidence—for the Nazca plate along the Peru-Chile trench<sup>15</sup>. The oblique subduction hypothesis can be rejected first, because the direction of convergence between the Cocos and the North America-Caribbean plates is well known 16,17, about 30° N that is quite perpendicular to the trench along most of its length; and second, because off Salvador and Nicaragua where the trench trends 140° N and the subduction is thus oblique, our sea-beam survey shows the horst and graben pattern parallel with the trench.

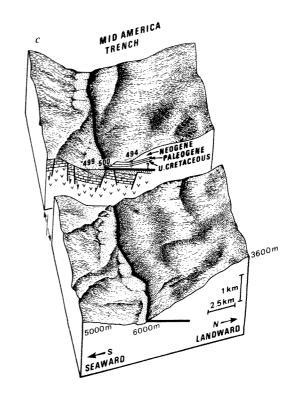

The sea-beam map shows that in the Leg 67 area (Fig. 2a), the Cocos structures reach the base of the continental wall without disturbing it. The main thrust fault of the subduction zone is apparently between the continental slope, where Upper Cretaceous sediments were drilled in hole 494 and a Cocos horst where the Lower Miocene oceanic crust was reached in hole 500. Thus, off Guatemala, neither the drilling results nor the sea-beam surveys indicate that a classical accretionary prism<sup>2</sup>

has developed. The presence at the base of the continental slope of such a sequence involving Upper Cretaceous and Tertiary in good stratigraphical order still needs explanation. It could be part of a large block slumped down the slope in recent times; however, sea-beam data (Fig. 2a) indicate that the base of the innerwall is perfectly rectilinear and that no scar is present. Anyway, the Upper Cretaceous sequence could belong to a block slumped in pre-Pliocene or Miocene times: that would mean that no accretion has occurred at least since then. Finally, the whole sequence of hole 494 could be considered as in situ implying no accretion for more than 70 Myr or that tectonic erosion removed younger accreted terranes. Only new drilling will eventually solve the problem. In the Leg 66 area (Fig. 2b, d) the infilling of the trench means that the contact itself between Cocos structures and the innerwall is not visible. However, the sea-beam map shows a more or less continuous ridge in the middle of the trench. Such a central crest was first described off Costa Rica, at the very end of the trench, from submersible observations<sup>18</sup>. Off Southern Mexico the ridge has a maximum relative height of 100 m and is flanked on its seaward side by an elongated depression in which anastomosed channels of the Ometepec deep-sea fan seem to converge. Central ridge and channel define the limit between a relatively smooth outer trench and an undulated and uplifted inner trench. Sea-beam data confirm previous interpretations from UTMSI multichannel seismic reflection lines crossing the same area11. Thus the central ridge appears to be located above the most recent emergence of the Benioff plane. In the inner trench, turbiditic reflectors are gently folded; in particular, south-east of the Ometepec canyon mouth both reflection data and sea-beam maps show the inner trench as a synformal depression (Figs 2b, d). Upslope, on the continental wall, the same ridgeand-basin morphology is present but shows far more contrast and is mature. Site 488, drilled on the first ridge at the base of the innerslope, reached tectonized turbidites 400-500 m higher than the present-day trench turbidites<sup>5</sup>. Finally, although no tectonic repetition has been confirmed by Leg 66 drillings, the data strongly suggest that trench sediments are being accreted to the Mexican margin off Acapulco<sup>5,6,11</sup>

Regarding the Cocos plate sea mounts related to off-axis volcanism are locally abundant and prevent development of a regular tectonic pattern. One of these sea mounts already mapped at 15°27'N-98°31'W off Mexico<sup>11</sup> is revealed by seabeam bathymetry as a nice collapse-pit volcano about 6.5 km in diameter (Fig. 3a). Other sea mounts are smaller regular cones belonging to the Cocos Ridge off Costa Rica and entering the subduction zone without apparent deformation (Fig. 3b).

Our sea-beam surveys confirm that at least two types of subduction are acting along the Mid America Trench. Off Guatemala (Leg 67 area) Cocos crust and sedimentary cover, as well as trench infilling are totally subducted beneath the continental margin. Some kind of tectonic erosion may have occurred to explain the atypical Upper Cretaceous sequence drilled at the base of the innerwall. In contrast, off Mexico (Leg 66 area) the thick pile of trench turbidites is actively accreted to the continental margin. The dual aspect of the innerwall does not appear on the seaward side of the trench. Close to the subduction zone, in both areas, the Cocos plate shows the same horst and graben pattern superimposed on inherited fractures formed at the East Pacific Rise. The fanning of magnetic anomalies on the Cocos plate 19 together with IPOD results indicate that the crust being subducted is progressively older in a southeastwards direction. The Tehuantepec Ridge breaks this continuity20, but does not mark a boundary between two different crustal provinces. Thus the Cocos plate does not seem to have a role in the type of subduction. Variability of other parameters could account for that phenomenon. For example, the convergence rate progressively increases from north to south<sup>17</sup> (being ~7 cm yr<sup>-1</sup> off Mexico and 10 cm yr<sup>-1</sup> off Guatemala); the dip of the Benioff zone is lower along the northern section of the trench 16; the trench fill is generally more important off Mexico than off Central America21. The last parameter is probably critical in the subduction. However, in the Mid America Trench, the terrigenous input closely depends on the morphostructure of the margin: on the northern section the narrow shelf is cut by numerous canyons that allow direct

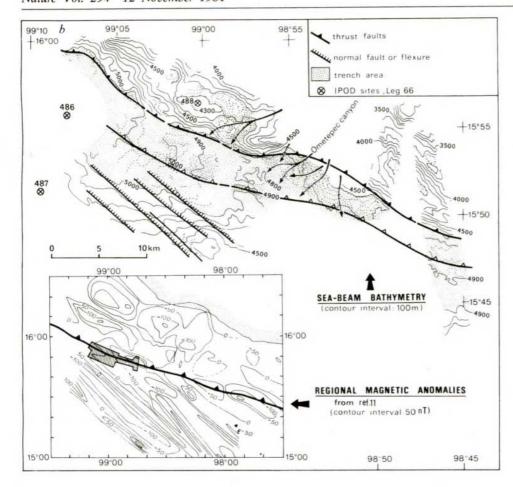

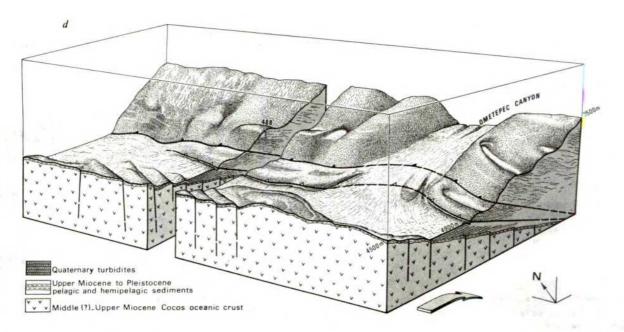

Fig. 2 Sea-beam map of a, the Leg 67 area and b, the Leg 66 area. (The original 10-m contour interval has been condensed to 100 m.) Schematic diagram of c, the Leg 67 area (after ref. 9) and d, the Leg 66 area.

transport to the trench of the clastics supplied by wide mountainous areas in the background (Sierra Madre del Sur); to the south, off Central America, the fluviatile input is far less important and most terrigenous material is trapped in the wide shelf basin. We know these two kinds of active margin belong to distinct plates (that is, the North America and the Caribbean plates). The boundary between both margins is located in the Gulf of Tehuantepec<sup>2,20</sup> that is exactly in the prolongation of the Polochic-Motagua fault system (Fig. 1). Thus, the northern and southern margins of the Mid America Trench directly reflects the geodynamic evolution of their own plate. For example, the

Mexican margin has experienced in Lower Tertiary times tectonic truncation and erosion that scraped off all Mesozoic accreted terranes as well as part of the older basement 11,12,22,23. In contrast, along the Central America margin a fore-arc basin has developed at least since the Palaeocene; moreover, a belt of Mesozoic ophiolites is still preserved on the margin 2,10. Regarding the present, tensional stress is responsible for the genesis of all known graben (Guatemala City, Nicaragua, and so on) south of the Polochic-Motagua fracture zone, while north of this boundary compressive deformations are occurring 24. We conclude therefore that not only simple parameters (such as

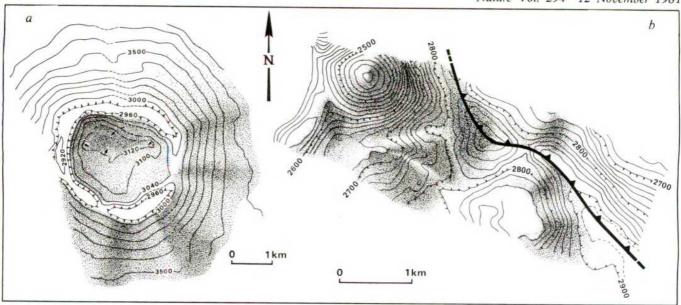

Fig. 3 Collapse-pit volcano off Mexico (a) and sea mounts on the Cocos ridge (b). See location on Fig. 1. Contour interval, 100 m on a; 20 m on b.

convergence rate and trench fill) account for the variation of the subduction process but also the properties (such as structure and kinematics) of the overriding plate. The Mid America Trench is

# Peralkaline volcanicity on the Eurasia Basin margin

D. J. Batten\*, P. E. Brown\*, P. R. Dawes†, A. K. Higgins†, B. Eske Koch‡, I. Parsons\* & N. J. Soper§

\*Department of Geology and Mineralogy, Marischal College, Aberdeen AB9 1A, UK †Grønlands Geologiske Undersøgelse, Øster Voldgade 10, DK-1350 København K, Denmark ‡Phytopalaeontologisk Afdeling, Geologisk Institut, Aarhus Universitet, DK-8000 Aarhus C, Denmark \$Department of Geology, University of Sheffield, Mappin Street, Sheffield S1 3JD, UK

The Kap Washington Group of post-Palaeozoic explosive volcanic rocks was discovered in 1969 on the north coast of Greenland. Although there have been uncertainties regarding their age and chemical character, they have featured prominently in geotectonic reconstructions of the Arctic regions-in recent interpretations as products of the Yermak hot spot, generated on the Nansen spreading axis during the opening of the Eurasia Basin. We present here new evidence which confirms the volcanicity as end-Cretaceous in age and of peralkaline type. We show that a direct connection with the Yermak hot spot is improbable and infer that the volcanic rocks were generated in a continental extensional rift environment before the break-up of the Laurasian plate in the Arctic. Their age helps to constrain the timing of this poorly understood event.

Aeromagnetic surveys conducted in the past decade 1-3 have established that the Eurasia Basin developed in Cenozoic time by ocean-floor spreading on the Nansen (Gakkel) Ridge, which detached an elongated continental fragment (the Lomonosov Ridge) from the Barents margin of the Eurasian plate (Fig. 1). There are problems concerning both the geometry and chronology of this phase of spreading. The geometrical problems arise from the uncertainties which still exist concerning the origin of the Amerasia Basin and Alpha Ridge2.4 and also the constraints imposed by the limited displacement permissible on the Nares Strait line5 on the geometry of opening of the Labrador Sea and Baffin Bay. Although recent magnetic anomaly superposition studies 1-4,6-9 have shed much light on the displacement patterns of the individual ocean basins around Greenland, it is clear that rigid-plate models do not lead to a complete geometrical solution and that within-plate strains must be important. Such strains are evidenced by the belt of Tertiary which extends from the Canadian Arctic (Eurekan Orogen 10,11) across northern deformation Archipelago Greenland 12,13 to Svalbard (West Spitsbergen Orogen 14).

The main chronological problem posed by the evidence from the Eurasia Basin is the time at which spreading was initiated. In dating magnetic anomalies and in relating on-land geological evidence to the history of the oceans, it is essential to use a recent polarity time scale. We adopt that of Hailwood et al. 15, noting that the commonly used Heirtzler et al.16 scale assigns ages to magnetic epochs in the late Cretaceous and early Tertiary which are too high by  $\sim 10\%$ . The oldest ocean-floor anomaly recognized in the Eurasia Basin is 24 (52 Myr, early Eocene) and a broad negative anomaly exists over the 50-100 km wide zone between it and the Lomonosov and Barents continental slopes, in which there is space to accommodate anomalies 25-28 (ref.

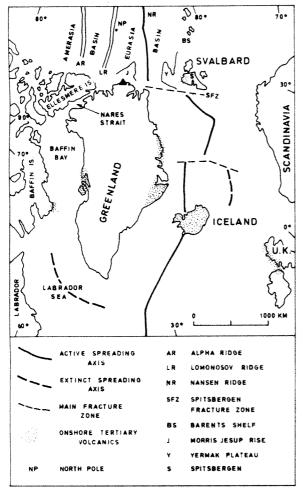

Fig. 1 Index map of the North Atlantic region. ▲, The location of the Kap Washington Group of volcanics in northern Greenland.

2). The crust flooring this zone could thus represent subsided continental crust, oceanic crust generated during a pre-anomaly 24 quiet period, or oceanic crust generated during the time of anomalies 25-28 (55-63 Myr, Palaeocene), whose magnetic expression was subsequently erased. This uncertainty should be seen in the light of the recently suggested history of the Amerasia Basin where seafloor spreading anomalies 34-19 (Cretaceous to mid-Eocene) are deemed identifiable between the Lomonosov Ridge and Alpha Ridge<sup>4</sup>.

Notable features in the present context are the aseismic submarine plateaus off northern Greenland (Morris Jesup Rise) and Svalbard (Yermak Plateau). These are thought to be constructional features produced by enhanced basaltic discharge from a Yermak hot spot situated at the junction of the Nansen Ridge and the Spitsbergen Fracture Zone<sup>3</sup> (Fig. 1). High-amplitude magnetic anomalies are associated with these plateaus, and they are bracketed by ocean-floor anomalies 13-18 (35-40 Myr, late Oligocene-early Eocene). This is thought to represent the period of maximum hot spot activity after which the subsiding plateaus were rifted apart by continued spreading. It has been proposed<sup>3</sup> that the volcanic province on the north coast of Greenland (Kap Washington Group<sup>12,17</sup>) is an early manifestation of this hot spot activity. If this were the case, the age of the volcanic rocks would provide an indication of the time of initiation of the hot spot volcanism, and thus of the onset of spreading in the Eurasia Basin. However, our data on the age and chemical character of the Kap Washington Group volcanics reported here demonstrate that the eruptives represent the products of peralkaline rift volcanism that predates the spreading history of the Eurasia Basin and thus the eruptives are unlikely to be directly associated with the Yermak hot spot.

The Kap Washington Group volcanic rocks outcrop at about 83°30'N on the north coast of Greenland at the edge of the

North Greenland fold belt, where they have a chronological position postdating the mid-Palaeozoic diastrophism of the fold belt but predating its Tertiary reactivation. Limited field observations in  $1969^{12.18}$  have been supplemented by field work in  $1979^{19}$  and  $1980^{20}$ . The outcrop of the volcanic rocks is limited to  $\sim 150 \text{ km}^2$  (Fig. 2), but considerable offshore extension may be indicated by the Morris Jesup Rise magnetic anomaly 3.21, although the nature of the rocks responsible for the anomaly is not known.

The extrusive volcanic rocks form southeasterly inclined sequences; they are non-metamorphic but locally show shearing and crushing and in places cleavage. The thickness of the exposed volcanic sequence is at least 5 km. It is composed of prominent pyroclastic rocks, including coarse breccias, finely bedded airfall tuffs, accretionary lapilli tuffs and welded ashflow tuffs, as well as both basic and acidic lavas. Some intrusive rock types are present, mainly felsic dykes and small plugs. The upper boundary of the volcanic sequence is a thrust contact with Lower Palaeozoic metasediments of the fold belt; thrusts also disturb the volcanic succession and bring in wedges of Carboniferous and Permian strata of the Wandel Sea Basin (Fig. 2).

Hitherto unpublished chemical data for material collected in 1969<sup>18</sup> and new petrographical data for recently collected material<sup>20</sup> demonstrate that the Kap Washington Group volcanics represent a peralkaline suite. The 1969 material is mainly rhyolitic and is difficult to characterize chemically; on a silica/alkali plot the rocks fall, not unexpectedly, in the subalkaline field. The single available analysis of a basic flow is thoroughly alkaline. The 10 analyses of rhyolitic material (SiO<sub>2</sub> range 66-75%) show appreciable alteration of major element composition and there is a marked variation in the Na<sub>2</sub>O/K<sub>2</sub>O ratio (total alkalis  $\sim 8.5\%$ ). CaO varies from 0.02 to 1.83 and Al<sub>2</sub>O<sub>3</sub> is between 10 and 18%. However, two samples show normative acmite—a clear indication of peralkalinity—and the trace element composition, particularly with respect to the relatively high values of Nb, Zr and Y, conform to those values normal for peralkaline rocks<sup>22</sup>. Petrographical results indicate that basalts, riebeckite trachytes and riebeckite comendites or pantellerites are the prominent lava types. Some basalts have a strongly developed flow texture and may overlap into the compositional field of hawaiites. The trachytes contain anorthoclase, ill-formed riebeckite and quartz in the flow textured groundmass. The more siliceous lavas have a variable riebeckite content and include flow banded and spherulitic varieties. The presence of the soda amphibole riebeckite establishes the peralkaline character of the Kap Washington Group.

The Kap Washington Group volcanic rocks conformably overlie black shales and sandstones which contain fragmentary plant debris. While no microfossils have been isolated from the sediments, a few angiosperm leaf fragments indicate a mid-Cretaceous or younger age. The available angiosperm leaf fragments are not determinable at either genus or species level. One small, nearly entire leaf specimen is a very primitive morphological type appearing in the Lower Cretaceous (Albian) floras of the eastern USA and Portugal (Proteaephyllum Fontaine and similar form genera). Another is a leaf fragment of an advanced pinnate angiospermous leaf type with percurrent nervils appearing in the Upper Cretaceous and continuing through the Tertiary. The primitive leaf type makes a Cretaceous age probable for the shale in question. The advanced leaf type does not permit an age older than mid-Cretaceous. However, with the very limited material available this can only be a tentative age.

Other black shales are interbedded with the pyroclastic rocks some 3 km above the base of the volcanics and several samples have been subjected to palynological investigation. The microfossils recovered are generally in a very poor state of preservation and few can be identified. Bisaccates, smooth-walled triradiate spores and some distinctive angiosperm pollen grains, identified as species of Aquilapollenites, Mancicorpus and Triprojectus, have been recorded, but all other identifications are questionable. Fortunately, the named genera have restricted

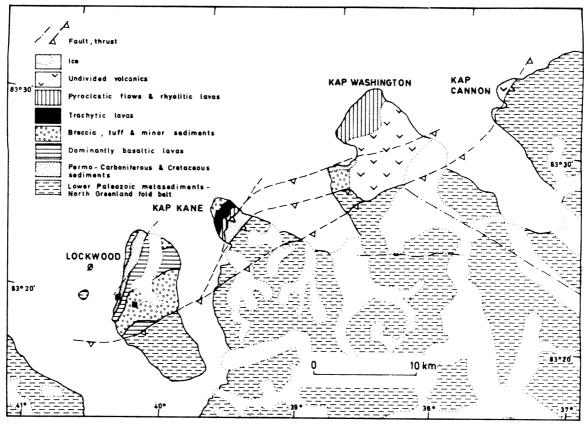

Fig. 2 Geological map of the total outcrop of Kap Washington Group volcanics. , Localities of the fossiliferous shales.

stratigraphical ranges and a late Cretaceous Campanian or Maastrichtian age is indicated; that is 75-65 Myr on the stratigraphical time scale. The upper limit is in close agreement with an earlier Rb-Sr whole-rock age of  $63 \pm 2$  Myr on five rhyolitic samples23, a result which had previously been regarded as unreliable on technical grounds. An age for the volcanicity at, or just before, the Cretaceous-Tertiary boundary is adopted here.

The characteristic tectonic environment of peralkaline volcanism is one of crustal extension and attenuation, so that their most abundant development is in association with regional doming and rifting<sup>24</sup>. Evidence of crustal extension immediately preceeding the extrusion of the Kap Washington volcanics is provided by alkali dolerite dykes and sills<sup>13</sup>. These cut the early Cretaceous and Carboniferous-Permian sediments, as well as older rocks of the North Greenland fold belt, but fail to penetrate the Kap Washington Group volcanic rocks<sup>25</sup>. These dykes, like the volcanics, show alteration and some shearing due to Tertiary tectonism. K/Ar whole-rock determinations show a range of apparent ages, although the most reliable of these away from areas of known Tertiary tectonism lie between 82 and 66 Myr (ref. 26). The dyke swarms are regarded as late Cretaceous in age.

The composition of the Kap Washington volcanics illustrates that the tectonic regime in the Barents Shelf-Greenland region in late Cretaceous time was extensional, as indeed it was in the entire region from the Sverdrup Basin of Arctic Canada through northern Greenland to the northern Barents Shelf. The palaeontological dating of the Kap Washington Group reported here places the beginning of the active spreading in the Eurasia Basin as probably no earlier than the Cretaceous-Tertiary boundary (perhaps as early as 75 Myr). The various reconstructions of the Barents Shelf margin before the seafloor spreading 1,3,4,9,13 place Svalbard close to northern Greenland and it has been suggested that the Kap Washington volcanics and even the earlier basic dykes are manifestations of the Yermak hot spot3. On the grounds of both their age and composition, we would not relate the Kap Washington Group or the basic dykes directly to the Yermak hot spot; the dykes and

volcanics are late and end-Cretaceous in age, respectively, while the first manifestation of hot spot activity in the ocean floor is at anomaly 18 time (40 Myr, late Eocene). The geographical association of the alkalic rift magmatism and later hot spot activity may well have petrogenetic significance, but this problem must await petrological studies of the Kap Washington volcanics and also sampling of the hot spot rocks from the submarine plateaus. Further consideration of Cretaceous-Tertiary magmatic and tectonic events in northern Greenland and their relationships to the history of adjacent ocean basins is presented elsewhere1

The paper is published with the permission of the Director of the Geological Survey of Greenland, Copenhagen.

# Migration of late Cenozoic volcanism in the South Island of New Zealand and the Campbell Plateau

#### C. J. Adams

Institute of Nuclear Sciences, Department of Scientific and Industrial Research, Lower, Hutt, New Zealan&

In late Cenozoic volcanics of eastern Australia, Wellman and McDougall¹ have shown a remarkable southward migration pattern of major shield volcanoes of alkaline olivine basalt association which they relate to movement of the continental crust over a fixed mantle hot-spot. Contemporaneous tholeiite lava field provinces do not show a similar pattern. Following their general selection criteria¹, I believe a similar situation emerges for New Zealand examples. In the South Island of New Zealand and the adjacent Campbell Plateau and Chatham Rise are several late Cenozoic volcanic centres that rest on a peneplain in Mesozoic and Palaeozoic granites and metamorphic rocks²-³, which is partly mantled by late Cretaceous to mid-Tertiary shallow marine sediments⁴-⁵. These major centres of late Cenozoic alkalic volcanism show an eastward decrease in age from ~28 Myr to ~0.5 Myr, presumably reflecting movement of a linear mantle source with respect to the Pacific Plate.

The volcanic centres are widely scattered and three volcanic associations are present: (1) Several major shield volcanoes of alkaline olivine basalt association, for example, Banks Peninsula, Otago Peninsula, Auckland and Campbell and Chatham Islands. (2) Very minor and restricted tholeite, for example, Timaru Basalt. (3) A calc-alkaline andesite volcano at Solander Island (probably related to active eastward subduction of the Indian plate below Fiordland). Brief geological notes for these volcanoes are compiled in Table 1 and age distributions shown in Fig. 1. In defining the age trend, only data from major alkaline olivine basalt centres are used, that is, the first group described above.

Although the data are sparse, there is an eastward decrease in age for the volcanic centres, and although there are no marked chains of volcanoes, there seems to be a predisposition for

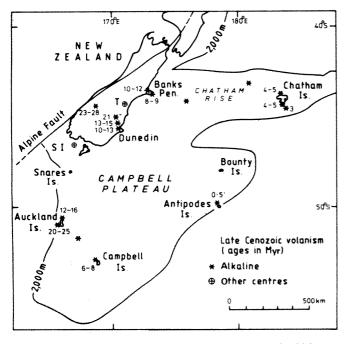

Fig. 1 Age data for centres of alkaline volcanism of mid-late Tertiary age in southern New Zealand and Campbell Plateau. SI, Solander Island; T, Timaru Basalt.

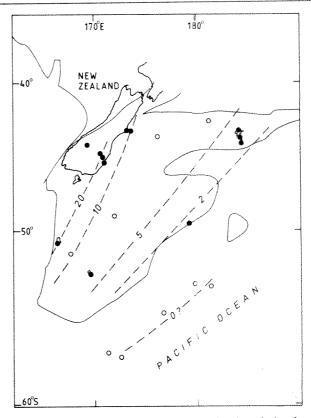

Fig. 2 Approximate locus of alkaline volcanism during late Tertiary on the basis of age data summarized in Fig. 1 from major volcanic centres dated (●). Possible submarine volcanic edifices, of similar age and type (○)<sup>4,5,29</sup> but undated.

volcanism to occur, at any one time, within a geographically restricted belt. The centres form neither arcs (as, for example, in the case of calc-alkalic volcanism) nor linear chains that arise from 'hot-spot' volcanicity. Using these age data Fig. 2 shows approximate isochrons which form a fan-shaped set beginning at 20 Myr ago, crossing the South Island in an NNE/SSW direction and rotating to a present NE/SW position close to the Campbell Plateau continental slope. This migration parallels the late Cenozoic movement of the New Zealand continental crust with respect to the active mid-oceanic spreading centre in the southwest Pacific (that is, an anticlockwise rotation of 60° about a pole approximately 65° S, 140° E).

Thus the location of the alkaline volcanism seems to be directly related to the passage of a mantle source below. At the surface there is evidence that the volcarism is locally controlled by major tectonic features: for example, Miocene NNE/SSW reverse faulting in east Otago<sup>6</sup> and recent NE/SW faults in the Antipodes Island and Campbell Plateau margin7. It is possible that the locus and style of faulting are themselves an expression of the passage of the hot mantle source below. A more speculative suggestion is that broad regional uplifts in the Oligocene-Miocene in Otago<sup>8</sup> and more recently on the Auckland/Campbell Island platforms4 might also reflect this process. The mantle source in this case cannot be regarded as a single 'hot spot'. similar to, for example, that which produced the Hawaiian volcanic island chain, or the slightly more diffuse source beneath the east Australian Cenozoic volcanoes. In the New Zealand-Campbell Plateau example, the mantle source responsible for the Cenozoic volcanism forms a relatively narrow (~100-200 km) linear belt, and is 1,000-1,500 km long throughout its course beneath southern New Zealand and the Campbell Plateau region. The movement of the mantle source corresponds closely to known late Cenozoic motion of the Pacific Plate with respect to the mantle. Hatherton indicated a similar migration pattern for the late Cenozoic-Quatenary calc-alkaline volcanic belts of the North Island of New Zealand formed at the Indian/Pacific Plate boundary. Using the poles and movement

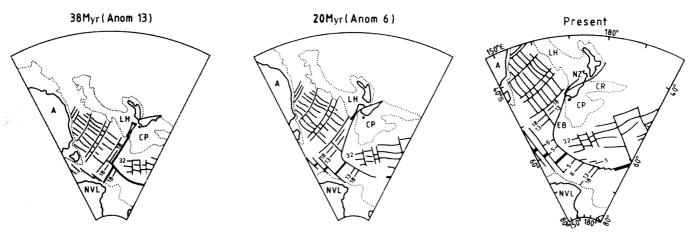

Fig. 3 Present day seafloor magnetic anomaly pattern and reconstructions of the south-west Pacific region 20 Myr and 38 Myr ago from Figs 13, 14 and 15 of ref. 30. A, Australia; CP, Campbell Plateau; CR, Chatham Rise; EB, Emerald Basin; LH, Lord Howe Rise; NVL, North Victoria Land, Antarctica; NZ, New Zealand.

rates deduced from seafloor spreading data, one can show that the mantle source responsible for the alkalic volcanism of the southern New Zealand region must now lie to the south-west of the Campbell Plateau margin and in the southwestern Pacific Basin. In this way a presumed 'zero' isochron is shown in Fig. 2 and it is intriguing that this lies close to prominent submarine features interpreted by Summerhayes<sup>4</sup> as possible volcanic seamounts. However, these have never been sampled or dated.

Similarly, the earlier history of the mantle source can be deduced from known mid-Cenozoic plate motions. The oldest and westernmost alkaline igneous activity is in west Otago, where a late Oligocene basaltic and lamprophyre dyke swarm occurs. Thus a mantle source must have originated there, or immediately to the west and before the late Oligocene.

It is likely that the long linear mantle source is related to a process of major reorganization of the Indian-Pacific-Antarctic plate motions in the southern New Zealand region in early-Oligocene times (~38 Myr; Fig. 3), and particularly to the formation of the Moonlight Aulacogen<sup>8,10</sup> at the southwestern margin of the Pacific plate. The development of this aulacogen controlled Oligocene sedimentation in the Emerald and Solander Basins (at the western margin of the Campbell Plateau) and the on-land extension northward into the Waiau Basin and Moonlight Tectonic Zone up to the Alpine Fault. The dimensions of the mantle source inferred from the pattern of volcanic centres would certainly be compatible with a linear tensional feature such as the Moonlight Aulacogen. The sub-crustal processes producing this aulacogen also possibly provided a mantle source for subsequent alkaline volcanism. However, immediately after this, a new phase of late Cenozoic seafloor spreading occurred in the southwestern Pacific (Fig. 3). Thus the continental crust of southern New Zealand and the Campbell Plateau began to move northwestwards over the mantle source and the subsequent alkaline volcanism is now expressed in a pattern of eastward migrating centres. The origin and generation of this new mantle source in relation to the early Cenozoic history is discussed in a new geophysical model of the region by Farrar, Adams and Dixon (in preparation).

I thank Ed Farrar for his help in assembling the age compilations and plate tectonic history of the region.

# Strontium isotopic resolution of magma dynamics in a layered intrusion

#### C. M. Gray

Department of Geology, La Trobe University, Bundoora, Victoria 3083, Australia

#### A. D. T. Goode

Exploration Department, The Broken Hill Proprietary Co. Ltd, Camberwell, Victoria 3124, Australia

Kalka is one of about 14 major layered mafic-ultramafic intrusions forming the Giles Complex in central Australia<sup>1</sup>. The stratigraphical section of the Kalka Intrusion passes from a basal pyroxenite zone (450+ m) through norite and olivine gabbro zones (3,500 m) to an uppermost anorthosite zone  $(800 + m)^2$ . Further resolution into 21 cyclic units is derived from repeated mineral crystallization sequences and cyclical variation in plagioclase and olivine compositions. A conventional interpretation would have a basaltic magma progressively fractionating as crystallization proceeded from mafic base to leucocratic top, with periodic resetting to less evolved states by fresh incursions of primary magma or by convectional overturn within a sealed magma chamber. However, the reconnaissance isotopic data reported here indicate development of a more complex open system. High initial <sup>87</sup>Sr/<sup>86</sup>Sr ratios in conjunction with normal 143Nd/144Nd ratios demonstrate massive contamination by country rock within the main part of the intrusion<sup>3</sup>. Furthermore, great variation in Sr initial ratios from 0.7049 to 0.7088 suggests substantial changes in magma composition beyond those induced by fractionation. Similar isotopic heterogeneity in the Newer Gabbros of Scotland<sup>4</sup> and the Bushveld Complex<sup>5</sup> has been attributed to variable contamination or the emplacement of magma batches of differing composition.

The present first detailed examination of the mechanism of isotopic variation in Kalka concentrates on the striking facies relationship between the norite and olivine gabbro zones. The norite zone (NZ) is the major component of the intrusion with a uniform clinopyroxene norite lithology reaching a maximum thickness of 3,500 m. Plagioclase composition shows an overall

upward variation from An<sub>75</sub> to An<sub>60</sub> broadly independent of the substantial separation into lower and upper subzones by the interleaved olivine gabbro zone. The much thinner olivine gabbro zone (OGZ) is totally enclosed within the body of the NZ and has a maximum thickness of 600 m and a strike length of 6.5 km (Fig. 1). It consists of an alternation of orthopyroxene gabbros similar to the rocks of the NZ and lesser olivine gabbro horizons, Plagioclase (An<sub>82-68</sub>) and olivine (Fo<sub>86-69</sub>) compositions oscillate as a function of stratigraphical position although co-crystallizing phases have been separated in the cumulate succession by differential gravity settling<sup>2</sup>. The facies link between the OGZ and NZ is expressed in the former by gradational boundaries defineable only on the appearance of olivine, and lateral interfingering of prominent bands into the NZ. The base of the OGZ is displaced to progressively higher stratigraphical levels towards the east and is laterally more extensive at these higher levels (a traditional 'transgressive' stratigraphical relationship in conventional sediments).

Initial 87 Sr/86 Sr ratios of rocks in a vertical section through the transition from the lower NZ to the OGZ are given in Table 1 and Fig. 2. The boundary is marked by a change from relative uniformity of initial ratio in the lower NZ at ~0.7078 to a cyclical variation in which values fall as low as 0.7068. The upper stratigraphical limit of the cycles lies beyond the sampled interval, but is probably the top contact of the OGZ. Eventually, the overlying section of the upper NZ saw a return to the initial ratio of its lower counterpart in the 0.70784 value of a reconnaissance gabbronorite sample. Overall, the continuous isotopic fluctuations of the OGZ can be described as a series of downward excursions from the general high value of the NZ. Overall variations in the total NZ itself reveal a small, gradual decrease in initial ratios from 0.7082 to 0.7073 from the base to the top of the zone. The petrological significance of the results is best seen in Fig. 2 through the correspondence of the onset of isotopic variation and the appearance of the olivine that defines the OGZ (olivine is rare in the 1,000 m of the underlying NZ). There is also an antipathetic decline in orthopyroxene, and a partial link between plagioclase and olivine compositional changes and the isotopic curve.

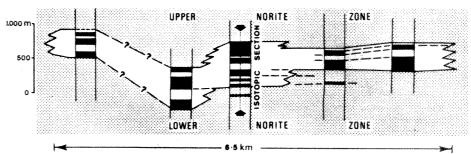

It is axiomatic that variations in Sr isotopic composition are due to physical processes and the only plausible explanation in this case is the mixing of materials with differing  $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$  ratios.

While the Nd-Sr study showed that primary basaltic magma and country rock granulite were the ultimate mixing components<sup>3</sup>, the absence of a discrete high-Si phase within the intrusion or other bodies in the Giles Complex points more to an interaction between primary magma (low <sup>87</sup>Sr/<sup>86</sup>Sr ratio) and contaminated magma (high <sup>87</sup>Sr/<sup>86</sup>Sr ratio) as the direct cause of isotopic fluctuations. Because the bulk of rocks within the intrusion show evidence of contamination, it is presumed that contaminated magma dominated the chamber and that primary magma was volumetrically minor and introduced from outside.

Given a low 87Sr/86Sr ratio in primary magma, any phase of decreasing initial ratio leading to an isotopic minimum (A, B, C of Fig. 2) can be attributed to a fresh incursion into the chamber and mixing with the established magma body. Incorporation of primitive magma could also lead to transient undersaturation and short bursts of olivine crystallization at that time (Fig. 2). Increases in initial ratio can be accounted for in two ways. If the

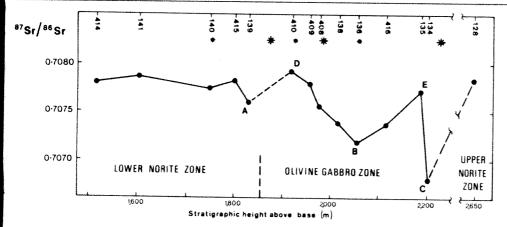

Fig. 2 Isotopic variation in the transition from the lower norite zone to the olivine gabbro zone, Kalka Intrusion. Sample numbers are shown along the top axis (major olivine component indicated by large asterisk, minor olivine component by small asterisk). Location of the section is shown in Fig. 1.

magma body were continuously mixed and isotopically homogeneous at any one time, the only explanation would involve addition from outside of material with a higher <sup>87</sup>Sr/<sup>86</sup>Sr ratio, either as direct contamination by wall rock or an influx of more contaminated magma. Accordingly, fluctuations in isotopic composition would reflect the interplay between the low and high <sup>87</sup>Sr/<sup>86</sup>Sr ratio sources; but while plausible, such a mechanism would probably produce random variations in contrast to the more regular observed pattern. Rather, the periodic return to a relatively constant isotopic ratio suggests that the new magma pulses were interacting with an almost infinite reservoir of contaminated magma; that they initially affected isolated aliquots of this reservoir, but were eventually absorbed by the reservoir. Increases in initial ratio, such as to D and E of Fig. 2, would then be due to a return to the background value of the intrusion.

The preferred model begins at the end of lower NZ time with the Kalka magma chamber filled by a well mixed contaminated basaltic liquid of relatively low density (<2.66)6 as a result of considerable crystallization of the pyroxene that accumulated in the pyroxenite zone; it is precipitating the two pyroxenes and plagioclase of the NZ with the high <sup>87</sup>Sr/<sup>86</sup>Sr ratio of 0.7078. A small pulse of primary magma enters the chamber and floods the floor due to its higher density. In moving across the floor the influx partly mixes with the adjacent resident magma forming a hybrid, which, still with a higher density than the main body of magma, forms an isolated layer that dominates the basal crystallization zone (evidence for basal crystallization in Kalka has been presented elsewhere<sup>2</sup>). The precipitated phases now reflect the composition of the hybrid: <sup>87</sup>Sr/<sup>86</sup>Sr ratios decrease and a short burst of olivine deposition as an olivine gabbro layer marks the beginning of crystal fractionation. The details of the petrological changes induced are determined by the nature of

the magma influxes. For example, sequential small pulses over a period of time will produce the gradual decline to minimum B (Fig. 2) whereas a single major pulse produces the abrupt drop to C.

The facies relationship between the OGZ and NZ is due to the restricted ponding of the magma pulses at low points on the floor of the intrusion: at any stage only part of the accumulative interface is disturbed and changes in the position of the low points with time can account for the eastern lateral migration of the main OGZ up-section (Fig. 1). The correspondence of the maximum lateral extent of the OGZ, the most magnesian olivine and the most calcic plagioclase, and the minimum initial <sup>7</sup>Sr/<sup>86</sup>Sr ratios in the upper parts of the OGZ are consistent with the greatest relative volumes of fresh magma injections being added to the system at that time. Ultimately, convectional mixing within the chamber as a whole disperses the residual hybrid, with crystallization reverting to the initial NZ state to await further magma pulses. At the same time, incorporation of the hybrid slightly lowers the background 87Sr/86Sr ratio of the main body of magma.

Independently, Huppert and Sparks<sup>7,8</sup> have proposed a similar model on fluid dynamical grounds thereby providing the physical basis of the processes described above. In particular, they demonstrate the formation of a stable basal layer by the incoming batch of magma and the eventual convective dispersal of the layer on cooling when density equilibration occurs. The link between petrological, fluid dynamic and isotopic approaches augurs well for the future elaboration of the evolution of layered intrusions and can give a more specific explanation of the origin of some types of macroscopic layering and cyclic units.

We conclude that the lithological transition from a monotonous gabbronorite sequence to a zone of vertically and

Sr isotopic ratios were measured at La Trobe University using a 22-cm radius solid-source mass spectrometer of modified Clement design. Uncertainties quoted in present-day  $^{87}$ Sr/ $^{86}$ Sr ratios are  $\pm 2\sigma$  mean. Measurements are relative to a value of  $0.71022\pm 4$  for the SRM 987 Sr standard. Initial ratios are calculated for an age of 1,150 Myr using  $\lambda$   $^{87}$ Rb  $1.42\times 10^{-11}$  yr $^{-1}$ . The age is an arbitrary mean for the 1,200–1,100 Myr time interval for emplacement of the Kalka Intrusion.

laterally restricted olivine gabbro horizons in Kalka correlates with the onset of cyclic fluctuations in initial 87Sr/86Sr ratios. Isotopic variability is attributed to dynamic mixing between the main body of contaminated magma in the chamber and incoming pulses of primary basaltic liquid. New magma batches ponded on the floor of the chamber temporarily dominating part of the basal crystallization zone; the result, transient olivine precipitation in laterally limited olivine gabbro layers having low Sr initial ratios. Ultimately, convective dispersal of the pools returned crystallization to its initial state with an accompanying rise in initial 87Sr/86Sr ratios to original or slightly reduced values

# Shallowing-upward cycles in the Middle Proterozoic Altyn Formation

#### **Brian White**

Department of Geology, Smith College, Northampton, Massachusetts 01063, USA

Phanerozoic carbonate rocks commonly contain cycles, a few metres thick, which were deposited during progressive shallowing of their oceanic environment1. Each cycle represents a deepening of water in a nearshore area, followed by the accumulation of sediments up to sea level. The causes of the water deepening which begins each cycle are rarely known. Possibilities include tectonic activity that affected the depositional basin and changes in ocean volume due to the expansion and contraction of ice sheets. I report here that similar cycles occur in the Middle Proterozoic Altyn Formation, part of the Belt Supergroup<sup>2</sup>. The cycles are probably related to vertical tectonic activity which influenced sedimentation in the Belt basin. The presence of shallowing-upward cycles in the Altyn Formation shows that such cycles are not confined to the Phanerozoic. Other Precambrian sequences should be examined to see if they too contain cycles. Where such cycles are found they may give important information about Precambrian tectonism and glaciation.

The Altyn Formation is exposed in the eastern part of Glacier National Park, Montana. The age of the formation may be estimated from geochronological data available for equivalent stratigraphic units. The Aldridge Formation of British Columbia has granodiorite intrusives which are at least 1,335 Myr old<sup>3</sup> and a sill in the lower part of the Prichard Formation in Idaho is 1,430 Myr old (R. E. Zartman, unpublished data). A best estimate of the age of the Altyn Formation is  $1,450 \pm 50$  Myr (J. Harrison, personal communication).

I have divided the Altyn Formation into the informal members shown in Fig. 1. Seventeen cycles have been identified in member A with an average thickness of 4.2 m and a range of 1.6-8.0 m. Member C has 12 cycles ranging from 1.6 to 4.6 m thick with an average of 2.5 m. Members B and E are quite homogeneous and devoid of stromatolites or other palaeoenvironmentally diagnostic sedimentary structures, and so far no cycles have been recognized in them.

An idealized and simplified version of the Altyn Formation cycles is shown in Fig. 2. The cycles are bounded by erosion The lowest part of each cycle usually has conglomerates and breccias composed of stromatolite fragments and pebbles of quartz and microcline. Dolarenites composed of peloids and intraclasts with variable amounts of quartz and microcline overlie the coarse basal layer. These dolarenites occasionally contain tabular cross-bedding. In the upper part very similar dolarenites alternate with stratiform stromatolites. The dolarenites commonly contain lenticular bedding and bimodal cross-bedding produced by the alternating flow of tidal currents. The stromatolites are very similar to those formed by smooth algal mats in modern lower intertidal zones of Shark Bay<sup>4,5</sup> and the Persian Gulf<sup>6</sup>. Smooth mat development is inhibited in Shark Bay and the Persian Gulf in areas where sand substrates are kept moving by strong tidal currents and waves<sup>5,6</sup>. Similarly the stratiform stromatolites of the Altyn Formation formed during relatively low energy conditions in the intertidal zone. This development of stromatolites was interrupted periodically by higher energy events, such as storms, which brought in sands from the adjacent subtidal zone. There is usually an upward increase in the ratio of stromatolites to dolarenites in each cycle, showing the decreasing influence of sand input from subtidal areas. Many stromatolites in the upper part of cycles have desiccation cracks and their upper surfaces are broken and disrupted to form intraformational breccias. These features are the result of increasing subaerial emergence and consequent drying of the sediments during the development of the upper part of the cycles. Each cycle represents deposition in progressively shallower water as sediments built up to sea level following an increase in water depth. Subtidal sands are overlain by lower intertidal sands and stromatolites which in turn pass upward into upper intertidal and supratidal stromatolites and intraformational breccias and conglomerates. This sequence is typical of cycles found in many Phanerozoic carbonate rocks1. There are few reported examples of shallowingupward cycles from rocks of Precambrian age. One possibility is the Strelley Pool chert which occurs in the 3,400-Myr old Warrawoona Group of Western Australia. This is an evaporitecarbonate sequence containing stromatolites. The Strelley Pool chert was deposited in shallow subtidal to intertidal environments<sup>7</sup>, and may represent an overall shallowing-upward sequence.

There are two important modifications of the idealized shallowing-upward cycle described above. Member A frequently contains discontinuous bioherms of columnar stromatolites near the base of the stromatolite-rich part of cycles. These commonly occur with conglomerates and breccias and overlie erosion surfaces. The columnar stromatolites were formed in localized higher energy environments in the lower intertidal zone, especially in tidal channels8. Many member C cycles contain arkoses

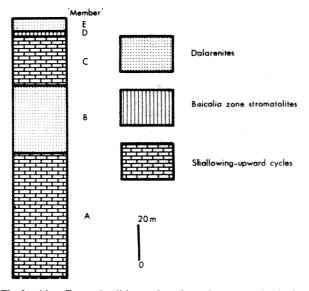

Fig. 1 Altyn Formation lithostratigraphy at the type section in the Appekunny Creek area, Glacier National Park, Montana

and shales, mainly in their upper parts. These terrigenous sediments were deposited in the upper intertidal and supratidal zones during flash flooding from the adjacent land area.

Further support for shallowing-upward depositional conditions in Altyn Formation cycles is provided by the former presence of evaporite minerals and the dolomitization of carbonate minerals. The evidence for evaporites includes silica pseudomorphs after gypsum crystals and anhydrite nodules, often with micrometre-sized gypsum and anhydrite preserved in the silica. The pseudomorphs contain length-slow chalcedony and flamboyant quartz, both of which replace evaporite minerals9,10

Cellular vugs filled by a centripetal sequence of silica, dolomite and calcite also occur. Some of these have a 'chickenwire' fabric which is characteristic of many modern and ancient anhydrite nodules 10. The formation of displacive gypsum crystals and anhydrite nodules is a diagenetic process which takes place in sediments as a result of intense evaporation of inter-stitial water in arid climates<sup>1,11</sup>. Gypsum crystals grow within sediments in the upper intertidal zone and anhydrite forms in the supratidal zone<sup>11</sup>. Sediments deposited in shallow subtidal or lower intertidal zones may be exposed later to upper intertidal or supratidal zone conditions as a result of progradation. Evaporites may form in these sediments because of this change of environment. The precipitation of calcium sulphate evaporite minerals in these sediments produces magnesium-rich interstitial waters which may lead to dolomitization of carbonate minerals<sup>1,11</sup>. In the Altyn Formation some columnar stromatolites and lower intertidal sediments contain replaced evaporites, showing that they were subsequently exposed to upper intertidal and supratidal conditions. All of the original carbonate minerals in each of the cycles are dolomitized as a result of these changes of environment. The dolomitization and formation of evaporites could have occurred only in shallowingupward cycles following sediment aggradation and the resultant seaward shift of the tidal zones.

Detailed studies show that many Phanerozoic carbonate rocks are cyclic and that each cycle represents aggradation during progradation, following a rapid transgression during which little sediment was deposited 1,12,13. The accumulation of a sequence of shallowing-upward cycles requires repeated transgressions, the cause of which is not well understood. Some possibilities include differential subsidence due to tectonic activity, eustatic sea level changes resulting from glaciation or changes in ocean volume caused by global tectonics<sup>14</sup>. The period 2,300-950 Myr ago was characterized by warm climates, with no evidence of glacial periods<sup>15</sup>. Thus glacial eustasy seems not to be the cause of cyclic sedimentation in the Altyn Formation. Opinions differ regarding the tectonic setting of the Belt depositional basin. One

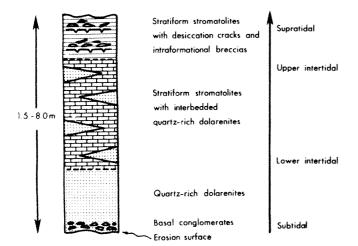

Fig. 2 Simplified shallowing-upward cycle representative of those found in the Altyn Formation.

view is that the basin was located at a rifted continental margin of the passive or Atlantic type 16-18, with vertical tectonic activity during deposition18. An opposing view suggests that the Belt basin was one of several, possibly fault-bounded, basins located within a continental craton 19,20.

Major contemporaneous faulting at the southern margin of the Belt basin strongly influenced sedimentation of the coarsegrained LaHood Formation<sup>21</sup>. This formation is equivalent in age to the Altyn Formation. Thus cyclic sedimentation in the Altyn Formation was probably related to intermittent subsidence caused by vertical tectonic activity, with sediment accumulation occurring in quieter periods between the tectonic events. Sedimentation elsewhere in the Belt basin was probably affected by tectonic activity. Detailed studies of other stratigraphic units of the Belt Supergroup may reveal cycles or manifestations of this tectonism. The presence of small-scale cycles in the Altyn Formation suggests that Precambrian sequences in other localities should be examined closely to see if they also contain cycles.

I thank E. J. Anderson and P. W. Goodwin, for stimulating discussions, J. E. Harrison for helpful criticism and C. C. Birney for critical reading of earlier drafts of this paper. Field and laboratory work supported by grants from the Aid to Faculty Scholarship Committee of Smith College.

# Superoxide dismutase is a prophylactic against alloxan diabetes

#### Kjell Grankvist, Stefan Marklund & Inge-Bert Täljedal

Department of Histology and Cell Biology and Department of Clinical Chemistry, University of Umeå, S-901 87 Umeå 6, Sweden

A single injection of alloxan<sup>1</sup>, or alloxan-like derivatives of uric acid<sup>2,3</sup>, kills the insulin-producing islet  $\beta$ -cells and causes diabetes mellitus in animals. This effect is probably mediated by a sequence of redox reactions involving the production of superoxide anion radicals in or near the  $\beta$ -cells<sup>4-8</sup>. Superoxide anions may also arise in inflammation 9-15, and islet inflammation often accompanies the outbreak of human diabetes16, perhaps following the combined onslaught of viruses and chemical agents on the  $\beta$ -cells<sup>17</sup>. We now report that injections of superoxide dismutase, an enzyme removing superoxide anion radicals, act prophylactically against alloxan-induced diabetes.

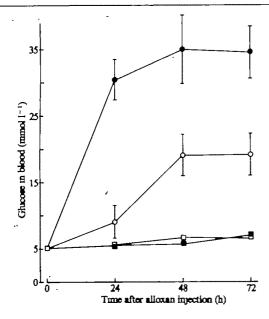

Fig. 1 Blood glucose concentrations in uninjected mice (0 h) and in mice intravenously injected with 25 (III), 50 (O) or 75 (Φ) mg alloxan per kg body weight Alloxan monohydrate (U S. Biochemical Corporation) was dissolved in a salt-balanced Krebs-Ringer buffer that had been adjusted to pH 4.0 by the addition of HCl. Female 3-month-old non-inbred mice (21-26 g) were mjected into a tail vem with alloxan solution at a dozage of 100 μl per 20 g mouse; control mice were similarly injected with physiological saline (□). Blood samples (25 μ leach) were taken from the cut tail tips 24, 48 and 72 h after injection, precipitated by ZnSO<sub>4</sub> and NaOH and assayed by an automatic glucose oxidase/peroxidase technique (Glox reagents, Kabl). Each point is the mean for five different mice; vertical bars show a.e. m. when larger than the symbol indicating the mean value.

When mice were injected into a tail vein with alloxan (50 or 75 mg per kg body weight), they became markedly hyperglycaemic within 48 h (Fig. 1). The diabetogenic effect was clearly dose-dependent, as alloxan at 25 mg per kg had no effect and 50 mg per kg produced a milder hyperglycaemia than did 75 mg per kg. With increasing concentrations, alloxan attacks cells other than the islet  $\beta$ -cells, for example, kidney and liver cells. The unequivocal, though not maximal, diabetogenic action of 50 mg per kg would provide optimum conditions for detecting any protecting or potentiating effect of the substances to be tested, and so this intermediate alloxan dose was selected for the subsequent experiments.

As shown in Table 1, in each of two separate series of experiments the diabetogenic action of alloxan was largely prevented if the mice had been injected with superoxide dismutase 12 h earlier. The enzyme preparation injected (provided by K.-E. Arfors, Pharmacia) was a purified yeast CuZnsuperoxide dismutase covalently linked to polyethylene glycol chains to yield a complex of molecular weight 100,000, so as to slow down its elimination from the circulation 16. Whereas the circulating half life of uncoupled superoxide dismutase in the rat is only 6 min (ref. 14), the enzyme-polyethylene glycol complex had an initial half life of about 2 h (Fig. 2). The elimination was more complicated than a first-order process, and after 12 h as much as 6% of the initial activity remained in the circulation. This remaining activity was about 10 times the basal activity of superoxide dismutase measured in the plasma of four untreated control mice  $(505\pm19 \text{ U ml}^{-1}; \text{ mean}\pm\text{s.e.m.})$ .

The antidiabetogenic action of superoxide dismutase was specific, as control experiments revealed no effect of inactivated superoxide dismutase—polyethylene glycol or of polyethylene glycol alone (Table 1). Furthermore, the enzymatically active superoxide dismutase—polyethylene glycol had no effect on blood glucose levels in healthy mice not treated with alloxan (Table 1).

According to the free-radical hypothesis of alloxan diabetogenicity, reduction of alloxan to dialuric acid in the islets is followed by autoxidation back to alloxan accompanied by the formation of superoxide anion radicals and hydrogen peroxide  $^{4-8}$ . Highly reactive hydroxyl radicals are then formed by a metal-catalysed 'Haber-Weiss reaction' that can be seen as the summation of the reduction of ferric ion by superoxide (Fe<sup>3+</sup> + O<sub>2</sub>.  $\rightarrow$  Fe<sup>2+</sup> + O<sub>2</sub>) and the Fenton reaction (H<sub>2</sub>O<sub>2</sub>+Fe<sup>2+</sup>  $\rightarrow$  OH·+OH<sup>-</sup>+Fe<sup>3+</sup>). The extreme and indiscriminatory reactivity of hydroxyl radicals can explain why alloxan rapidly affects a wide range of phenomena in the  $\beta$ -cells, including insulin synthesis<sup>19</sup>, insulin release<sup>8,20</sup>, cation pumping<sup>6,21</sup>, glucose metabolism and oxygen consumption<sup>22</sup>, Trypan blue exclusion<sup>6,23</sup> and mitochrondrial morphology<sup>24</sup>. In support of this hypothesis alloxan toxicity is counteracted *in vivo* by scavengers of hydroxyl radicals and *in vitro* by such scavengers<sup>6,23</sup> as well as by superoxide dismutase, catalase and a chelator of iron ions<sup>6-8</sup>. The present results represent further, and crucial, support for the hypothesis, as they confirm the

Table 1 Prophylaxis by superoxide dismutase against alloxan diabetes in mice

Drug injected before	Time between injections of SOD/PEG (or PEG) and alloxan		ose (mmol I <sup>-1</sup> ) NaCi
First experimental series			
None	_	$20.4 \pm 2.4 (5)$	4.8 + 0.1(9)
SOD-PEG, 200 mg per kg	· 12 h	$9.2 \pm 1.4^{*}$ (6)	$50\pm02(4)$
Inactivated SOD-PEG 200 mg per kg	, 12 h	$21.1 \pm 2.5 (5)$	$5.2 \pm 0.2 (5)$
Second experimental series			
None		$21.4 \pm 2.4$ (6)	$4.8 \pm 0.3(4)$
SOD-PEG, 250 mg per kg	12 h	$8.2 \pm 2.1*(6)$	$5.7 \pm 0.1 (6)$
Inactivated SOD-PEG 250 mg per kg	, 12 h	20.4±1.9 (6)	$5.4 \pm 0.2 (6)$
PEG, 250 mg per kg	12 h	$19.0 \pm 1.1 (5)$	$5.6 \pm 0.3 (5)$
PEG, 250 mg per kg	2 h	$17.9 \pm 1.2$ (5)	$5.1 \pm 0.3$ (5)

Mace were injected with alloxan (50 mg per kg) or NaCl, and blood glucose was assayed after 72 h as in Fig. 1. Before injection with alloxan or NaCl, groups of mice were injected into a tail vein with yeast CuZn-superoxide dismutase coupled to polyethylene glycol (SOD-PEG), with SOD-PEG that had lost 99.2% of its enzyme activity during prior exposure to  $\rm H_2O_2$  (ref. 6), or with uncoupled polyethylene glycol alone (PEG). The time elapsing between the injection of SOD-PEG or PEG on the one hand and alloxan or NaCl on the other was 12 or 2 h as indicated. All mice were firsted, with free access to water for 12 h before the alloxan or NaCl injection and for 3 h before the blood sampling. Results are given as mean values  $\pm$ s.e.m. for the numbers of animals stated in parentheses. In the two separate series, different batches of SOD-PEG were used.

two separate series, different batches of SOD-PEG were used.

\* The prophylactic effect of SOD-PEG against alloxan diabetes was against and, with P < 0.01 in either series of experiments (Student's *t*-test, two-tailed). Among the 11 mice injected with alloxan alone, the lowest and highest blood glucose values were 11.2 and 28.1 mmol  $1^{-1}$ . The corresponding range for the 13 mice injected with NaCl alone was 3.9–5.5 mmol  $1^{-1}$ . Among the 12 mice injected with alloxan after 200 or 250 mg per kg SOD-PEG, as many as 6 had blood glucose values in the range of 4.7–5.9; the remaining 6 values ranged over 8.5–17.0

postulated role of superoxide anion radicals in the diabetogenic action of alloxan *in vivo*. Even more important, apparently for the first time it has been possible to protect against alloxan diabetes by administering a drug several hours beforehand. This result may be of more than theoretical interest, as superoxide dismutase has already been established as a safe drug of potential value for the treatment of other diseases in humans<sup>26</sup>.

It has been suggested that the superoxide anion radical is relatively harmless in  $vivo^{27.28}$ , based on the relatively low reactivity of the radical with several classes of compound in vitro, and the assumption that other reductants might substitute for it in reducing the ferric ion in the Haber-Weiss reaction. Against this background our results seem important in demonstrating the high toxic potential of the superoxide radical in vivo, as well as in underlining the importance of an adequate protection against it. The results do not necessarily mean that  $\beta$ -cells are

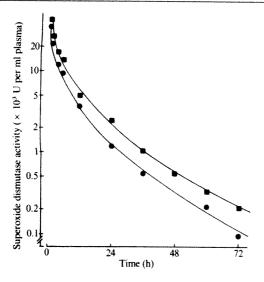

Fig. 2 Superoxide dismutase activity in the blood plasma of two mice at various times after an intravenous injection of yeast CuZn-superoxide dismutase coupled to polyethylene glycol; the drug was injected into a tail vein at a dosage of 200 mg per body weight. Samples (25 µl each) of whole blood were drawn from the tails and mixed with  $500\,\mu l$  of a solution containing  $150\,mmol\,l^{-1}$  NaCl and  $3\,mmol\,l^{-1}$  EDTA. After centrifugation, the supernatant was assayed for superoxide dismutase by the direct spectrophotometric method using KO<sub>2</sub> (ref. 29). One unit of enzyme activity corresponds to 4.2 ng of bovine CuZn-superoxide dismutase. Plasma levels were calculated by assuming an erythrocyte blood volume fraction of 40%. To show the elevation of enzyme activity produced by injecting SOD-PEG, the values in the figure have been corrected for the mean endogenous superoxide dismutase activity in mouse plasma (505 U ml<sup>-1</sup>).

especially sensitive to alloxan because they are extraordinarily sensitive to the harmful effects of superoxide radicals. It seems equally possible that the physiological specialization of the  $\beta$ -cells renders them unusually effective in reducing alloxan or in catalysing the iron-dependent formation of OH. from H<sub>2</sub>O<sub>2</sub> and O2.

# Nepotism among rhesus monkey brothers

#### D. B. Meikle

Either during or shortly after sexual maturation, male rhesus monkeys leave the social groups in which they were born and join other non-natal groups (refs 1, 2 and unpublished data). Here we report that males frequently transfer into the same social groups as their older maternally related brothers. Such brothers spent more time close to each other than to other males, formed alliances with brothers more frequently than with non-brothers and disrupted each other's interactions with oestrous females less frequently than expected by chance. They also spent more time in non-natal groups than did males who did not have a brother in the group. Length of time in a group is positively associated with male dominance rank<sup>1</sup> and probably with reproductive success. The data are consistent with proposals that brothers who behave nepotistically and noncompetitively have high inclusive fitness.

Data are presented from long-term census records and 339 h of focal-animal<sup>3</sup> observations (February 1978–February 1979) of 18 male rhesus monkeys who comprised seven sets of siblings: a quintet, a triad and five pairs. The subjects lived in four social groups containing ~200, 175, 160 and 110 animals (groups A, I, C and E, respectively). The four study groups and four other social groups were free-ranging on La Cueva, a provisioned 100-acre island off the south-west coast of Puerto Rico<sup>4</sup>. Three of the four study groups were introduced to the island in 1962, the fourth in 1969 and four smaller groups in 1975. One other group was introduced in 1962, but decreased in size and disintegrated by 1975. Each monkey had an identification tattoo of letters and numbers and the maternal relations were known for all animals in the four study groups4.

During 20-min observation periods, the frequency and duration of approaches within 2 m (excluding agonistic encounters) between the focal male and all other individuals in his group were recorded, as were all his involvements in agonistic encounters and his interactions with oestrous females. All but three of the subjects were observed for 51 periods. Two subjects died (G6 and N6, 21 and 33 observations, respectively) and one (CT5, 30 observations) was observed from mid-study. By comparing each subject's interactions with brothers and nonbrothers during only his set of observations, no bias is introduced by unequal samples of observations. For all subjects, equal numbers of observations were made during each of two time periods: 06.30-09.00 and 09.00-11.30 h.

Analysis of group transfer among young males suggested that they shifted into groups containing older brothers. Although males transfer preferentially into the non-natal group with the highest ratio of adult females to adult males<sup>1</sup>, less than half of the males that have ever joined a brother's group on La Cueva (n = 17) joined the non-natal group with the highest ratio. Each social group on La Cueva often came into contact with all other groups5 and there was no evidence that geographical location of groups influenced group transfer. In addition, no male who was transferring from his natal group had a brother in more than one non-natal group.

If we assume the distribution of males in non-natal groups to be random, the probability of a male's joining his brother(s) in

one of three study groups was 0.33. This expected probability was an overestimate for some males, because after 1975 there were four small groups that they could have joined (which did not contain older brothers of any transferring males). By assuming a larger probability, however, it is more difficult to reject the null hypothesis that group transfer is independent of kinship. Since 1962, there have been 31 males who had a brother in a non-natal group when they changed groups. Seventeen joined their brothers' groups while 14 did not ( $\chi^2 = 6.5$ , d.f. = 1, P <0.05). At the end of the study, 9 of 14 living males who had left their natal group and had an older brother in a non-natal group were in their older brothers' groups ( $\chi^2 = 6.2$ , d.f. = 1, P <0.05). Males from the same natal groups were not significantly clumped ( $\chi^2 = 13.69$ , d.f. = 11, P > 0.10).

Fourteen of the 18 subjects approached their brother(s) more frequently than they approached any other males (P < 0.05, sign test), and brothers spent more time within 2 m of each other  $(\bar{x} = 24.5 \text{ min})$  than of any other males  $(\bar{x} = 7.7 \text{ min}, P < 0.05,$ Mann-Whitney U). During focal observations 19 coalitions were formed between a subject and another male during a fight with a third male (Table 1). Of the 10 different subjects involved in a coalition, 9 more frequently aided a brother than a nonbrother (P < 0.05, sign test). Agonistic coalitions have been reported for several macaque species<sup>6-8</sup> and probably have a significant effect on the success of brothers in non-natal groups. This hypothesis is supported by the dominance rank history of the sibling triad G6, N6 and 8G. The oldest brother disappeared during a food shortage and several weeks later the middle brother (N6) was attacked and died from infection. The youngest brother (8G) immediately dropped four positions in the male dominance hierarchy, the only male to decrease more than one rank-position during the study.

When an oestrous female was soliciting or consorting with a male, she was often displaced from that male (or attacked) by another adult male (n = 156 disruptions, Table 2). For 13 of 15 subjects, the observed number of disruptions involving brothers was less than the expected value based on males randomly receiving or sending disruptions (P < 0.05, sign test). These data suggest that brothers avoided disrupting each other's sexual interactions.

During the colony's history, brothers who had been in the same group (n = 26) accrued more months in those groups  $(\bar{x} = 31.7)$  than did the 25 males who were not in their brothers groups ( $\bar{x} = 21.4$ , P < 0.05, Mann-Whitney U). This difference was not due to age, as the males who did not join their brothers' groups were older  $(\bar{x} = 8.7 \text{ yr})$  than those who did join their brothers ( $\bar{x} = 8.1 \text{ yr}$ ). Nor was the difference due to the maternally dependent ranks of the males9. Those from the topranking half of their natal group did not spend significantly more time in non-natal groups than those from the bottom-ranking half ( $\bar{x} = 26.2$  and 27.9 months, respectively).

As a male accrues time within a non-natal group, he increases not only the number of breeding seasons during which he can

Probability (P) of a brother sending or receiving a disruption = (no. ofbrothers subject has in group) ÷ (no. of reproductively active males in group -1). Expected frequency of a disruption involving a brother equals the product of P and the total number of disruptions. Sign decision is based on whether observed brother disruptions are greater or less than expected number of brother disruptions (P < 0.05, sign test).

father offspring, but also his dominance rank<sup>1,10</sup>. As there is a positive association between dominance rank and RS11,12, a male who accrues time (and therefore rank) in a group probably sires, on the average, relatively more offspring each breeding season (ref. 10 and unpublished data).

Affiliations among brothers have been described briefly for several nonhuman primates<sup>13,14</sup>. One possible mechanism by which brothers develop affiliative behaviours is attachment<sup>15</sup> which may result from their close association with their mother. This hypothesis is supported by the fact that the average age difference between brothers in the same groups was 1.7 yr, while that between brothers in different groups was 2.6 yr. Other data, however, suggest that monkeys raised in isolation from birth associate preferentially with unfamiliar siblings<sup>16</sup>. Hence, both kin recognition and attachment may result in nepotism. Whatever the mechanisms which result in affiliative behaviours among brothers, our data are consistent with the hypothesis that nepotistic brothers have high inclusive fitness, and Hamilton's model<sup>17</sup> remains a plausible explanation for the evolution of nepotism among rhesus monkey brothers.

# Opiates and clonidine prolong calcium-dependent after-hyperpolarizations

Takayuki Tokimasa\*, Kiichiro Morita\* & Alan North\*

Neurophysiology Laboratory, Department of Pharmacology, Loyola University Stritch School of Medicine, 2160 S. First Avenue, Maywood, Illinois 60153, USA

Opiates<sup>1,2</sup> and  $\alpha$ -agonists<sup>3,4</sup> bind to separate and structurally specific sites on neurones in the central<sup>1,3</sup> and enteric nervous systems<sup>2,4</sup>. One functional consequence of this binding is inhibition of cell firing<sup>5,6</sup>, which may be due to hyperpolarization of the resting membrane by opiates, such as has been observed in the guinea pig locus coeruleus<sup>7</sup> and myenteric plexus<sup>8</sup>, and by clonidine in the myenteric plexus9. However, the discharge frequency of many nerve cells is limited by the membrane hyperpolarization which follows a period of activity, and which is caused by a transient increase in the intracellular calcium concentration leading to the activation of a membrane potassium conductance<sup>10</sup>. Neurones of the guinea pig myenteric plexus exhibit such a calcium-dependent potassium conductance11-13. We now report that both opiates and clonidine prolong this calcium-dependent after-hyperpolarization at concentrations (100 pM-10 nM) which are considerably lower than those usually required to hyperpolarize the resting membrane. Such a prolongation of the after-hyperpolarization will limit the frequency of discharge of neurones without altering their resting potential. The nature of the effects of morphine and clonidine are of interest in view of the similarities between the anatomical distribution of binding sites for these two drugs and the close parallels between their pharmacological effects in animals and man.

Intracellular recordings were made for more than 60 neurones in myenteric ganglia isolated from guinea pigs<sup>12</sup>. The neurones were bathed in a physiological saline solution (see Fig. 1 legend) to which morphine, clonidine or other drugs could be added. Action potentials were evoked by passing brief depolarizing currents through the recording electrode. Most of the experiments were on neurones which showed long-lasting after-hyperpolarization following a single action potential (type 2 (ref. 12) or AH cells<sup>13</sup>). Type 1 cells<sup>12</sup> or S cells<sup>13</sup> only showed an after-hyperpolarization following a train of action potentials. The after-hyperpolarization following a train of action potentials (usually 10 Hz for 3 s) was completely eliminated by cobalt (3 mM) or by perfusion with calcium-free solution (Fig. 1).

Morphine (100 pM-10 nM) prolonged the after-hyper-polarization which followed a train of action potentials. The effect of morphine was concentration dependent in the range tested, and reversed within 5-10 min of washing with morphine-free solution (Fig. 2). Naloxone (1 nM) reversibly abolished the action of morphine. The prolongation occurred without marked change in amplitude or time course of the initial component of the after-hyperpolarization (see Fig. 2 legend), suggesting that morphine may inhibit the mechanism by which a neurone normalizes its free intracellular calcium concentration following the action potentials.

Doubling the extracellular calcium concentration or the application of tetraethylammonium bromide (1 mM), increased the duration of the after-hyperpolarization. Morphine was much less effective in further prolonging the after-hyperpolarization

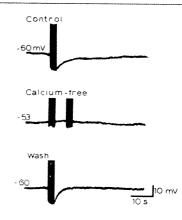

Fig. 1 Abolition of the hyperpolarization following a train of action potentials by removal of extracellular calcium ions. This and other figures are intracellular recordings of membrane potential. Depolarizing current pulses of sufficient amplitude to evoke action potentials were passed across the cell membrane (full spike amplitude is not shown). Each train consisted of 15 pulses at 5 Hz. Top trace, control recording. Resting potential, -60 mV. Middle trace, 20 min after changing to a solution containing no calcium and 5 mM magnesium. The cell membrane depolarized by 7 mV, but even two trains of action potentials failed to elicit any after-hyperpolarization. Bottom trace, 20 min after returning to the control solution. All intracellular recordings were done using techniques described elsewhere 12. Control perfusion solutions contained (mM): NaCl, 117; KCl, 4.7; CaCl<sub>2</sub>, 2.54; MgCl, 1.2; NaH<sub>2</sub>PO<sub>4</sub>, 1.2; NaHCO<sub>3</sub>, 25; glucose, 11, and were gassed with 5% CO<sub>2</sub> and 95% O<sub>2</sub>.

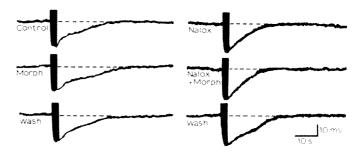

Fig. 2 Prolongation of the after-hyperpolarization by morphine (1 nM). Left: top trace, control recording; middle trace, 2 min after commencing perfusion with a solution containing morphine sulphate (1 nM); bottom trace, 10 min after washing with a morphine-free solution. Right: top trace obtained after several minutes in naloxone hydrochloride (1 nM); middle trace, 2 min after changing to a solution which contained naloxone and morphine (1 nM); bottom trace, 10 min after washing with control solution. Morphine had no effect in the presence of naloxone; in this and other experiments, naloxone itself slightly reduced the after-hyperpolarization. Maximum amplitude of after-hyperpolarization was not affected by morphine (1 nM); control, 17.5 ± 0.70 mV; morphine,  $18.4 \pm 0.53 \text{ mV}$  (mean  $\pm$  s.e., paired *t*-test, P > 0.05, n = 11). Time for decay to 50% ( $t_{50}$ ) or to 80% ( $t_{80}$ ) of peak amplitude was prolonged by morphine (1 nM): control,  $t_{50}$  = 12.2 ± 1.5 s; morphine,  $t_{50} = 16.0 \pm 2.0$  s (paired t-test, P < 0.01, n = 11). Control,  $t_{80} = 24.5 \pm 3.0$  s; morphine,  $t_{80} = 36.0 \pm 4.3$  s (paired t-test, P < 0.001, n = 11).

in the presence of an elevated (5.08 mM) calcium ion concentration (Fig. 3). Reducing the calcium ion concentration to one-half (1.26 mM) its control value decreased the duration of the after-hyperpolarization; in this case the effect of morphine became greater (Fig. 3). The lower calcium concentration may be much closer to that of 'free' calcium in the extracellular space of the nervous system<sup>14</sup>.

<sup>\*</sup>Present address: Department of Nutrition & Food Science, Massachusetts Institute of Technology, Room 37-311, Cambridge, Massachusetts 02139, USA.

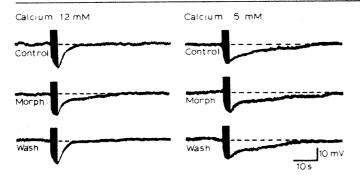

Fig. 3 Effect of morphine in high and low calcium concentrations. Left, recordings from the same neurone shown in Fig. 2, but after 30 min in a solution containing low (1.2 mM) calcium concentration. Top trace, control; middle trace, after 2 min perfusion with morphine (1 nM); bottom trace, wash. Right, further recordings from the same neurone, after 30 min in high (5 mM) calcium solution. Top trace, control; middle trace, after 1.5 min perfusion with morphine (1 nM); bottom trace, wash. The prolongation of the after-hyperpolarization by morphine was much more apparent when the after-hyperpolarization was shortened by reducing the calcium concentration.

Opiates inhibit the binding of calcium to brain synaptosomal membranes and the extent of this inhibition is reduced in high calcium solutions<sup>15</sup>. We speculate that occupation of the opiate receptor of myenteric neurones may lead to an inhibition of the binding of calcium to an intracellular site, perhaps on the inner surface of the membrane. If this site is normally important in the sequestration of calcium which enters the neurone during activity, such an inhibition would prolong the period of increased intracellular calcium and, therefore, the after-hyperpolarization. Such a mechanism could also underlie the hyperpolarization of the resting membrane observed with higher morphine concentrations8.

Clonidine (100 pM-10 nM) prolonged the after-hyperpolarization in a similar manner to morphine, although a larger proportion of neurones also showed a hyperpolarization of the resting membrane. This action of clonidine was prevented by phentolamine (100 nM). The similarity between the acute effects of clonidine and morphine may underlie the closeness of the pharmacological profiles of the two drugs. It is further possible that their identical mechanism of action offers an explanation for the efficacy of clonidine in ameliorating the signs and symptoms of opiate withdrawal<sup>6,1</sup>

# Calmodulin localization during capping and receptor-mediated endocytosis

J. L. Salisbury, J. S. Condeelis, N. J. Maihle & P. Satir

Department of Anatomy, Albert Einstein College of Medicine, Bronx, New York 10461, USA

The early response by lymphocytes to challenge with cell surface-directed ligand, such as antibody or concanavalin A (Con A), involves the clustering of initially diffuse ligandreceptor complexes into patches, followed by the gathering of these patches into a cap over one region of the cell and their endocytosis1-3. Using cells of the human lymphoblastoid line WiL2, we have previously shown that receptor-mediated endocytosis occurring at caps involves clathrin-coated vesicles and that the formation of such vesicles is sensitive to drugs such as trifluoperazine dihydrochloride (TFP) that affect calmodulin (CaM), the calcium-dependent regulatory protein of cells<sup>3</sup>. By indirect immunofluorescence, we demonstrate here that in WiL2, before surface-directed ligand challenge, CaM is distributed diffusely in the cell. On challenge, concurrent with capping of cell-surface receptors for Con A, CaM localization becomes concentrated in regions of the cytoplasm just below the cap. We show that CaM redistribution is sensitive to TFP and dependent on Ca2+ in the external milieu. Capping is mostly unaffected by TFP or removal of external Ca2+. Cytochalasin D (CD), on the other hand, blocks capping completely, but does not prevent the initial redistribution of CaM. These results are consistent with a functional role for CaM in clathrin recruitment to the cell surface beneath ligand-receptor complexes and an initial Ca2+ requiring, microfilament-independent event in receptor-mediated endocytosis.

Calmodulin has been implicated in the mediation of various cellular activities thought to involve transient fluxes of Ca<sup>2-</sup> signals<sup>4,5</sup>. In particular, CaM-Ca<sup>2+</sup> has been shown to regulate myosin light chain kinase of smooth muscle and non-muscle cells<sup>6-10</sup> and may be an important intermediate in the Ca<sup>2</sup> control of microfilament-based motility in such cells. Immunofluorescence techniques have been used to visualize the localization of CaM in a variety of cells 11-17. To study the intracellular distribution of CaM in WiL2 cells during Con A capping and endocytosis, we prepared rabbit antiserum against purified bovine brain CaM (Fig. 1a, b) as outlined by Wallace and Cheung<sup>18</sup>. This antiserum specifically identifies one polypeptide band, CaM, in a crude brain extract by a gel transfer peroxidase-antiperoxidase staining technique 19 (see Fig. 1). The antiserum has also been used in preliminary experiments specifically to immunoprecipitate WiL2 CaM metabolically labelled with <sup>35</sup>S-methionine (J. L. Salisbury and R. Green, unpublished observations). We further purified the anti-CaM IgG by affinity chromatography on a CaM-Sepharose column according to Dedman and co-workers<sup>11</sup> (see Fig. 1 legend) and, using the purified immunoglobulin as the primary antibody, we followed the reorganization of intracellular CaM during Con A receptor capping using double labelling techniques (Fig. 2). In these studies Con A receptors and CaM could be followed in the same cell using Con A covalently labelled with fluorescein isothiocyanate (FITC-Con A), which fluoresces yellow-green, and anti-CaM labelled with a secondary antibody, rhodamine-conjugated goat anti-rabbit IgG, which fluoresces red.

CaM localization during capping appears concentrated at sites of endocytosis. When WiL2 cells are fixed immediately after ligand challenge and labelled with anti-CaM (as described in Fig. 2g-i legend) they exhibit a diffuse cell-surface FITC-Con A localization (Fig. 2h) and a diffuse intracellular distribution of rhodamine-labelled anti-CaM (Fig. 2i) which is brighter than the diffuse low level of rhodamine fluorescence displayed by

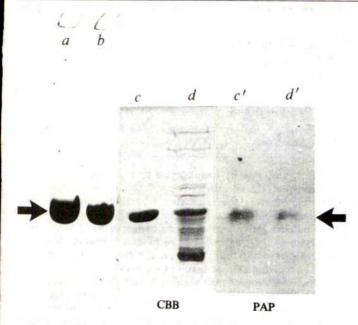

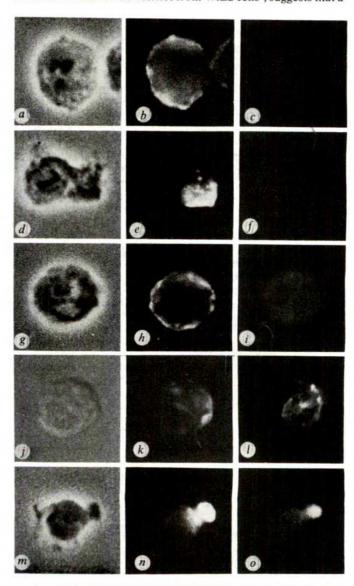

Fig. 1 Rabbit antiserum against bovine brain CaM was prepared according to Wallace and Cheung<sup>18</sup>. Track a is a SDS-polyacrylamide electropherogram showing a sample of the highly purified bovine brain CaM used to prepare the dinitrophenyl (DNP)–CaM shown in track b, which was subsequently used as the antigen. The antisera contained non-precipitating anti-CaM antibodies which were detected by the peroxidase–antiperoxidase staining of anti-CaM serum-treated nitrocellulose transfers from 15% polyacrylamide microslab gels containing 0.1% SDS into which either purified (tracks c, c') or heat-treated crude CaM containing extracts from bovine brain (tracks d, d') were electriphoresed. Shown here is a Coomassie brilliant blue stained gel (CBB) and a peroxidase–antiperoxidase (PAP) stained transfer of a companion gel. CaM is the band near the centre of each track (arrows). Specific anti-CaM antibody was affinity purified from the IgG fraction of immunized rabbit antiserum by adsorption on to native CaM covalently linked to Sepharose 4B. Following an extensive wash, specifically bound anti-CaM IgG was eluted with a pulse of 0.2 M glycine pH 2.8, adjusted to pH 7.5 with 1 M phosphate buffer and dialysed against phosphate-buffered saline (PBS).

Fig. 2 Indirect immunofluorescent localization of CaM during Con A receptor capping. Indirect immunofluorescent localization of anti-CaM binding sites was carried out using the affinity purified anti-CaM and rhodamine-conjugated goat anti-rabbit IgG (Cappel Laboratories). WiL2 cells were challenged with FITC-Con A (10 µg ml-1) to induce capping of Con A receptors. At various times after FITC-Con A challenge the cells were briefly fixed with formaldehyde, extracted in -20 °C absolute acetone, reacted with affinity purified anti-CaM, washed with PBS and reacted with rhodamine-conjugated goat anti-rabbit IgG. After washing, the cells were observed using a Zeiss photomicroscope equipped for UV epi-illumination. The cell-surface distribution of FITC-Con A and the intracellular localization of rhodamine-labelled anti-CaM could be separately visualized on or in the same cell by switching to the appropriate excitation filter, beam splitter and barrier filter (Zeiss BP 450-490, FT 510 and BP 520-560 for FITC and BP 456/10, FT 580, LP 590 for rhodamine). a-c, WiL2 cell challenged with FITC-Con A, immediately fixed and treated with preimmune antiserum followed by rhodamine-labelled goat anti-rabbit IgG showing the diffuse ring-like surface localization of FITC-Con A receptors (b) and the control level of background rhodamine fluorescence (c). The same level of back ground fluorescence was observed when the primary antibody was omitted entirely or when anti-CaM was first preabsorbed with excess CaM. d-f, WiL2 cell treated as in a-c but first allowed to cap the FITC-Con A receptors (e) at 37 °C before fixation, again illustrating the control level of background rhodamine fluorescence (f). g-i, WiL2 cell challenged with FITC-Con A, immediately fixed and treated with the affinity purified anti-CaM IgG followed by rhodamine-labelled goat anti-rabbit IgG. The FITC-Con A is diffusely located at the cell surface (h) while the rhodaminelabelled anti-CaM is diffuse throughout the cytoplasm (i). j, k, WiL2 cell treated as in g-i but first allowed to begin capping the FITC-Con A receptors at 37 °C for 30 min before fixation. Note the lateral redistribution of FITC-Con A receptors at the cell surface (k) accompanied by a dramatic reorganization of the intracellular anti-CaM binding sites beneath the capping FITC-Con A (1). m-o, WiL2 cell treated as in g-i but first allowed completely to cap the FITC-Con A for 1 h before fixation. Here the rhodamine-labelled anti-CaM has reorganized within the cytoplasm (o) beneath the tight FITC-Con A cap (n). The same pattern of specific anti CaM localization was observed when whole immune serum was substituted for affinity purified serum. Each row, left to right, shows the same cell. a, d, g, j, m, Light micrograph; b, e, h, k, n, FITC-Con A fluorescence; c, f, i, l, o, rhodamine fluorescence. All  $\sim \times 1,460$ . Fluorescence micrographs were recorded using Tri-X (Kodak) film and developed in Diafine for 5 min.

control cells labelled with preimmune serum (Fig. 2c). We interpret this to indicate that CaM is uniformly distributed throughout the unstimulated cell in which Con A receptors are diffuse and that receptor-mediated endocytosis is occurring only at a basal rate. When the cells are allowed to cap the FITC-Con A at 37 °C for 30 min before fixation (Fig. 2j-l) a dramatic redistribution of intracellular anti-CaM binding sites occurs. As FITC-Con A receptors begin to move laterally towards one region of the cell surface (Fig. 2k), the originally diffuse anti-CaM binding sites also move to regions in the cytoplasm just beneath the large clustered regions of Con A and sometimes also appear at a focal region near the cell centre (Fig. 21). Control cells allowed to cap FITC-Con A (Fig. 2e) and then treated either with preimmune serum instead of anti-CaM, omitting primary antibody, or by preabsorbing anti-CaM with excess CaM, still show only diffuse low-level rhodamine staining

When cells are allowed to cap the FITC-Con A completely (Fig. 2n), rhodamine-labelled anti-CaM binding sites become further reorganized in the cytoplasm beneath the cap (Fig. 2o). This suggests that after ligand challenge, CaM is bound to and moves with some cytoplasmic structure that itself co-caps with the ligand. As indirect immunofluorescence studies<sup>19</sup> indicate that actin and myosin co-cap with certain surface receptors and co-isolate with Con A caps from *Dictyostelium*<sup>20</sup>, one potential CaM binding structure is the microfilament network of the cell cortex. Alternatively, the finding that endocytosis accompanies capping and is sensitive to CaM-directed drugs<sup>3</sup> and that CaM co-isolates with coated vesicles from WiL2 cells<sup>3</sup>, suggests that a

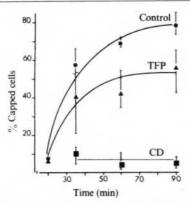

Fig. 3 Kinetics of capping after challenge with Con A and the effects of cytochalasin D (CD) and trifluoperazine (TFP) on capping. WiL2 cells were incubated in PBS ( $\bullet$ ), cytochalasin D (Sigma),  $10 \,\mu g \, \text{ml}^{-1}$  ( $\blacksquare$ ), or trifluoperazine (Smith Kline & French),  $15 \,\mu \text{M}$  ( $\blacktriangle$ ), for 10 min, challenged with  $10 \,\mu g \, \text{ml}^{-1}$  FITC-Con A and allowed to cap the receptor-ligand complexes at  $37 \,^{\circ}\text{C}$ . At various times after ligand challenge, cells were fixed and fields of 20--30 cells photographed using the fluorescence microscope. Each point represents the mean value of % capped cells for a minimum of  $100 \, \text{cells}$ , the bars represent the maximum range for individual\_fields. A capped cell is defined here as one which has redistributed the FITC-Con A, clearing at least half of its cell surface of label.

second potential CaM binding site is the membrane of clathrincoated pits and vesicles. We have investigated these suggestions in a series of experiments using drug inhibitors of capping and endocytosis.

We have previously reported<sup>3</sup> that the cytochalasin derivative dihydrocytochalasin B inhibits capping of cell-surface IgM by WiL2 cells. However, it has no apparent effect on the recruitment of clathrin coat material to ligand–IgM complexes and only partially reduces endocytosis of the complexes<sup>3</sup>. Similarly, although CD (10 µg ml<sup>-1</sup>) inhibits Con A capping almost completely (Fig. 3), this drug does not inhibit eventual endocytosis of ligand (to be published elsewhere).

Trifluoperazine dihydrochloride at low concentration (10–25 μM) is a potent and highly specific inhibitor of CaM-mediated processes<sup>21–24</sup>, and binds to CaM with high affinity in the presence of Ca<sup>2+</sup> (refs 22, 23). It inhibits CaM stimulation of brain phosphodiesterase<sup>22,23</sup> and adenylate cyclase<sup>23</sup>, inactivates CaM regulation of smooth muscle contraction<sup>24</sup>, and in WiL2 cells, significantly blocks entocytosis of surface receptors<sup>3</sup>. An important effect of TFP is the inhibition of clathrin recruitment to clustered receptor complexes, which suggests that clathrin recruitment is a CaM-regulated event<sup>3</sup>. TFP does not prevent capping of either Con A receptors (Fig. 3) or receptor-IgM in WiL2 cells<sup>3</sup>, in contrast to its effect in other cells<sup>25</sup>, but it does reduce the final percentage of tightly capped cells by about one-third (Fig. 3).

The differential effects of CD and TFP on receptor capping have allowed us to explore whether CaM redistribution on ligand challenge is obligately coupled to capping. Figure 4a-c illustrates the reorganization of intracellular CaM during capping by WiL2 cells in normal conditions and corresponds to Fig. 2j-l. When WiL2 cells are incubated with CD (10 µg ml<sup>-1</sup>) but otherwise treated as in Fig. 4a-c, Con A receptor capping is inhibited (Figs 3, 4e). The FITC-Con A is patched and by 30 min is mostly still at the cell surface although it is eventually internalized3. Anti-CaM binding sites are not diffuse in the CD-treated cells. Rather, rhodamine-labelled anti-CaM appears as numerous 'hot spots' in the cytoplasm (Fig. 4f), many of which lie directly beneath patches of FITC-Con A at the cell surface (Fig. 4e, f). In the absence of ligand challenge, CD treatment does not result in CaM redistribution (not shown). Therefore, CaM reorganization follows ligand challenge and does not depend on receptor capping. Receptor capping and CaM redistribution are separable events.

When WiL2 cells are incubated with TFP (15  $\mu$ M) and treated as in Fig. 4a-c, Con A receptor capping still occurs (Fig. 4h) in most of the cells, albeit in a lower percentage than the controls (see Fig. 3). Nevertheless, in these TFP-treated capped cells

anti-CaM staining is diffuse throughout the cell (Fig. 4i). The rhodamine-labelled anti-CaM is considerably brighter in TFP-treated cells than in any other treatment. We do not know why this is so; in these conditions TFP autofluorescence is undetectable. Perhaps TFP binding to CaM in the cytoplasm unmasks antigenic determinants on the molecule. In any event, these results clearly show that capping can occur in the presence of TFP, independently of CaM redistribution.

To probe the effect of Ca<sup>2+</sup> on these processes, we have begun chelator experiments. When WiL2 cells are incubated in conditions where the external free Ca<sup>2+</sup> concentration is held below 10<sup>-7</sup> M by inclusion of the calcium chelator EGTA in the external medium, capping of Con A receptors proceeds normally (Fig. 4k), in agreement with the findings of other workers<sup>2</sup>. In these conditions anti-CaM binding sites again remain diffuse (Fig. 4l). These results suggest that Ca<sup>2+</sup> is a necessary intermediate in the coupling of capping and CaM redistribution.

The observations reported here, taken with our earlier studies<sup>3</sup>, support the suggestion that receptor-mediated endocytosis operates under the control of CaM-Ca<sup>2+</sup> signals that involve transient fluxes of Ca<sup>2+</sup> across the plasma membrane at sites of ligand-receptor clusters. In our experiments the structural redistribution of CaM after ligand challenge and presumably CaM-Ca<sup>2+</sup> complex formation corresponds to the formation and distribution of coated endocytotic vesicles rather than to microfilaments. In this regard, it is important to recall that CaM appears to be an intrinsic component of coated vesicles isolated from WiL2 cells<sup>3</sup> and from brain<sup>26</sup>. Although in normal conditions coated vesicle formation is closely coupled to microfilament formation and function, this coupling is not

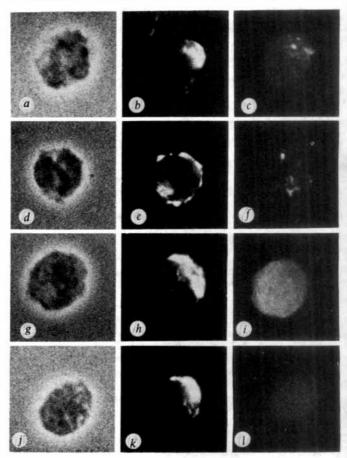

Fig. 4 Receptor capping and CaM redistribution are separable events. WiL2 cells were incubated in PBS (a-c), cytochalasin D,  $10 \mu g \text{ ml}^{-1} (d-f)$ , trifluoperazife,  $15 \mu M (g-i)$  or EGTA, 5 mM (j-i) for  $10 \min$ , challenged with  $10 \mu g \text{ ml}^{-1}$  FITC-Con A and allowed to cap the receptor-ligand complexes for 30 min at  $37 \, ^{\circ}\text{C}$ . Cells were fixed and then processed for anti-CaM staining as described in Fig. 2 legend. Each row, left to right, shows the same cell. a, d, g, j, Phase micrographs; b, e, h, k, FITC-Con A fluorescence; c, f, i, l, anti-CaM rhodamine fluorescence. All  $\sim \times 1,460$ .

obligatory. Two sites of action of CaM-Ca<sup>2+</sup> are interesting potential control points in this process: (1) The activation of myosin light chain kinase for acceleration if capping. This might explain the partial inhibition of capping seen on TFP treatment. (2) The recruitment of clathrin coats to the membrane

Our understanding of the mechanism of T-cell help in antibody production in the mouse has been improved by the production of long-term lines of T cells, either using T-cell growth factor (TCGF or IL-2) or by creating T-cell hybridomas. Such cells have been shown to produce non-antigen-specific 1,2 or antigenspecific helper factors3 with genetically restricted or unrestricted activity<sup>1-3</sup>. However, the factors are still not well characterized. We have examined the role of human T-helper cells and their soluble factors in inducing antibody production, initially in a xenogeneic system, using mouse B cells4. Using a human in vitro secondary antibody response system for influenza virus we have investigated the effect of helper factors on human B cells. We report here the production of long-term cultures of antigenspecific human helper cells. Both the cells and the high-potency antigen-specific helper factor (HF) which they produce act on human B cells in a genetically restricted manner. Preliminary mapping of the restriction indicates associations, but not identity, with HLA-DR.

Table 1 Cell membrane phenotype of F, T-cell line

Human peripheral blood lymphocytes (PBLs) were prepared on a Ficoll-Hypaque gradient, then suspended at  $10^{-7}\,\mathrm{ml^{-1}}$  in RPMI 1640 containing 10% fetal calf serum (FCS) and mixed with two volumes of 8-(aminoethyl isothiouronium bromide hydrobromide)-treated sheep red blood cells (SRBC). After incubation at 4 °C, E\* cells (T cell-enriched suspensions) were separated from non-rosetting cells (E\*; T cell-depleted suspensions) by centrifugation through a Ficoll–Hypaque gradient. Red cells were removed by hypotonic shock. E $^*$  cells were cultured for 7 days at a concentration of  $1\times10^6$  ml $^{-1}$  with A/X31 (5  $\mu g$  ml $^{-1}$ ) in the presence of 10% horse serum in 50-ml Falcon flasks. Dead cells were then removed on a Ficoll-Hypaque gradient and the cells (containing 20-40% blasts) were re-cultured at a concentration of  $1\times10^5$  ml $^{-1}$  in RPMI+10% FCS supplemented with TCGF medium diluted to an optimal concentration (~25%). The supernatants were prepared by culturing  $1\times10^6$  pooled human tonsil cells from different donors with  $2~\mu g~ml^{-1}$  PHA in RPMI-5% human serum for 48 h. PHA was removed from TCGF medium by passage over a column of Sepharose 4B to which rabbit anti-PHA immunoglobulin had been coupled<sup>17</sup>. PHA-depleted medium was no longer able to induce the proliferation of PBLs. TCGF medium was filtered and stored at -20 °C. Every 3-4 days, medium was removed by centrifugation and cells re-seeded at  $1 \times 10^5$  cells ml<sup>-1</sup> in fresh TCGF medium in the absence of antigen.  $F_7$  T cells have been kept growing for >4 months. The average doubling time is 48 h. Aliquots of  $F_7$  cells  $(2\times10^5)$  were incubated for 30 min on ice with saturating concentrations, previously determined by titration, of monoclonal antibodies (culture supernatant or purified immunoglobulin) washed three times in HEPES-buffered RPMI medium with 5% FCS and stained for 30 min on ice with human immunoglobulin-absorbed and immunoabsorbentpurified fluorescein isothiocyanate-conjugated (FITC) sheep anti-mouse immunoglobulin antiserum. After a further three washes the cells were either examined by fluorescence microscopy or analysed by Becton-Dickinson FACS I or IV. Controls and precautions to minimize non-specific binding have been described previously<sup>18</sup>. Monoclonal antibodies used were: UCHT1 (against all mature peripheral human T lymphocytes<sup>18</sup>); Leu 2a and 3a (gifts from Becton-Dickinson); anti-HLA-DR (DA2)<sup>19</sup> (gift from Dr M. Crumpton); OKM1 and OKT11 (gifts from Dr G. Goldstein); and BA-1 (ref. 6) gift from Dr J. Kersey. Polyspecific FITC sheep anti-human immunoglobulin antiserum was prepared in our laboratory—this brightly stains human peripheral blood B lymphocytes. ND, not determined.

Peripheral blood lymphocytes from donors (laboratory volunteers) known to respond to strain A influenza virus (A/X31) and strain B, Hong Kong B virus (HKB), were cultured with A/X31 for 7 days before addition of human TCGF depleted of phytohaemagglutinin (PHA). Several lines have been obtained which, after 4-6 weeks of growth, displayed stable characteristics. The surface characteristics of one of these cell lines, F<sub>7</sub>, are shown in Table 1. After 6 weeks, essentially all the cells were T cells (UCHT1+, E+, and OKT11+, OKM1-) of the helper type Leu 3a<sup>+</sup>, 2a<sup>-</sup> (see Table 1). A high, but variable proportion of cells stained with antisera to HLA-DR throughout culture. No staining was seen with conventional anti-immunoglobulin antisera or the monoclonal anti-B lymphocyte serum BA-1 (ref. 6). Analysis of these lines earlier in their development revealed different results, in that some cells were Leu 3a<sup>-</sup>, 2a<sup>+</sup>, but these cells were lost spontaneously during culture.

The helper activity of the T-cell lines was assayed on autologous B cells and monocytes using erythrocyte rosette-depleted cells' in the absence of TCGF. In a typical experiment (Fig. 1) with the F<sub>7</sub> cell line, 65 days after initiation of culture, optimal help was obtained with  $5 \times 10^2$  cells, compared with  $10^5$  fresh T cells from the same donor (before culture). Moreover, the number of antigen-responding helper T cells was  $\sim 1:10-1:30$ , as measured by limiting dilution, which is in the range of that observed for a cloned helper T-cell line in the mouse2. Note that in this and most other experiments, excess helper line cells markedly inhibited the response. The helper property of the cell

line remained after 5 months of culture. The specificity of the helper line was demonstrated by the markedly diminished capacity to respond to HKB compared with uncultured T cells (Fig. 1). Specificity was verified by the lack of a response to varicella-zoster virus, and in 'bystander' experiments with mixtures of A/X31 and HKB (data not shown).

We investigated the mechanisms of help by the cell lines. The best studied— $H_2$  (a similar cell line from another donor) and  $F_7$ —yield high potency supernatants. These could be obtained from T cells cultured alone without TCGF, but higher titres of HF were obtained when autologous irradiated  $E^-$  cells plus antigen (A/X31) were added (Fig. 2). Again, maximum help was obtained at low percentages of HF (0.1–1%), whereas higher concentrations were inhibitory. This help was specific, as the response of HKB was not influenced. Supernatants produced in the presence of A/X31 also demonstrated no bystander effect, as previously noted for mouse TCGF lines<sup>7</sup>. (This effect is the induction by specific antigen of a nonspecific factor which

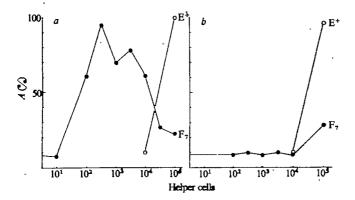

Fig. 1 Helper activity effected by A/X31-specific F<sub>7</sub> T-cell line. The method described by Callard and modified by Zanders et al. was used to assay the ability of washed TCGF-free F7 cells to help E cells in producing antibodies to A/X31. E and E cells were separated by centrifugation through a Percoll (Pharmacia) d = 1.08gradient after incubation at 4°C with AET-treated SRBC. Red cells were removed by hypotonic shock. E cells (1×105) were cultured in round-bottomed 96-well microtitre plates with various amounts of either fresh  $E^+$  or  $F_7$  T (after 65 days of culture) cells in 200  $\mu$ l of RPMI-1640 (Gibco) supplemented with 10% horse serum and glutamine (200 mM), and A/X31 (1  $\mu$ g ml<sup>-1</sup>; a), or HKB (0.2 µg ml<sup>-1</sup>; b). Cultures performed in triplicate were maintained at 37 °C for 6 days, then washed and recultured in 0.1 ml RPMI medium containing 5% FCS and glutamine. Supernatants were collected after 24 h and assayed for anti-A/X31 or anti-HKB antibodies by a solid-phase enzyme immunoassay. Antibody production was determined by reading the absorbance at 405 nm of the transformed substrate of alkaline phosphatase; actual amounts of antibody were calculated by referring to a standard curve<sup>20</sup>. Results are expressed as a percentage of the optimal response induced by 10<sup>3</sup> E<sup>+</sup> cells. For each experimental point, the s.d. was <25% of the mean value. The amount of antibody detected in these experiments ranged from 45.4 to 114 ng ml<sup>-1</sup> (100% A). Backgrounds (E<sup>-</sup> alone) ranged from 4 to 11% of maximal values.

induces B cells to respond, if their appropriate antigen is present.) However, high concentrations of  $F_7$  cells or HF from the supernatant of  $F_7$  ( $S_7$ ) sometimes gave small but significant nonspecific help, as shown in Figs 1, 2.

Most reports of antigen-specific HFs indicate that they are not genetically restricted in their action (for review see ref. 8) but some HFs do seem restricted<sup>9,10</sup>. This was investigated using E-cells (a mixture of B cells and monocytes) which were either autologous, HLA-DR-semi-compatible or incompatible with the  $F_7$  cells. HF derived from two cell lines ( $H_2$  and  $F_7$ ) showed a genetically restricted helper activity stimulating only B cells of certain donors. As shown in Table 2 for  $F_7$  cells and helper factor ( $S_7$ ), autologous and both parental B cells were helped, whereas

Either  $F_7$  T cells or supernatants (prepared in the presence of irradiated  $E^-$  cells and A/X31) were assayed as described previously  $^{20}$  on  $E^-$  cells sharing either two, one or no HLA-DR antigens with  $F_7$  T cells. The data are expressed as a percentage of the optimal response provided by  $E^+$  cells autologous to the relevant  $E^-$  cells. For each donor the maximal help provided by the optimal number of  $F_7$  T cells and optimal concentration of supernatant  $(S_7)$  is given. Each individual was HLA typed on two occasions with identical results. All donors were tested at least twice over a wide range of cell and factor concentrations. The 2/7 responder has been tested 4 times with  $F_7$  cells and twice with  $S_7$ .

most HLA-DR-incompatible donor B cells (8 out of 9) were not. All HLA-DR4 B cells tested (10) were strongly helped by  $F_7$  cells and  $S_7$  HF, suggesting either identity or a strong linkage disequilibrium between the restriction element and DR4, as only one of the DRW6-positive B cells except for the parental DR6/7 cells were helped. The latter result could be explained by the wide heterogeneity of the DRW6 group 11. However, B cells from one of nine DR-incompatible donors were consistently helped by  $F_7$  to produce anti-A/X31 antibodies.

This indicates a close association, but not indentity, between the locus coding for T-B restriction and the HLA-DR locus. The nature of the component expressing the genetic restriction is unknown, but as HLA-DR antigens seem to have homology with I-E/C products<sup>12</sup>, the restricting element detected in our system may be the equivalent of the mouse I-A region, which is known to be intimately involved in T-helper cell and factor function<sup>3,13</sup>. The p29, 34 molecule recently described by Nadler et al.<sup>14</sup> would be a likely candidate.

The results obtained with long-term cultured T-cell lines specific for influenza strain A/X31 indicate clearly that, just as in the mouse, antigen-specific helper cells can be propagated long term (for over 4 months) using TCGF. A report of human, non-antigen-specific T cells has been published elsewhere15 The type of helper cell cultured varies: Schreier and Tees 1.7 and Watson<sup>2</sup> have reported erythrocyte-specific T cells which, while responding to antigen specifically, did not help in a specific manner. In contrast, Eshar et al.3 described a helper line specific for poly(L-tyrosine-L-glutamic acid)-poly(D,L-alanine)-poly(Llysine) (TGAL) and P. Erb (personal communication) has derived a keyhole-limpet haemocyanin-specific helper line which produces antigen-specific HF. It seems likely that these contrasting results, which closely parallel discrepancies concerning mechanisms of T-cell help, reflect different subpopulations of helper cells.

Our results have been obtained with a long-term cell line, and not with clones. Many attempts to clone these cells at low numbers, in the presence of feeder cells, have failed. It is

Concentration of F7 supernatant

Fig. 2 Helper activity of F<sub>7</sub> supernatants. Long term-cultured T cells (F<sub>7</sub>) after 80 days of culture  $(1 \times 10^6 \text{ ml}^{-1})$  were incubated cells  $(F_7)$  after 80 days of culture  $(F_7)$  and  $(F_7)$  alone (O) or with optimal dose of antigen A/X31  $(\blacksquare)$  or with a strength of the 18 h in TCGF-free medium containing 10% horse serum. The supernatants were collected by centrifugation, filtered and stored at -20° C. They were assayed at various concentrations (expressed as a percentage) for their ability to help the production in vitro of anti-A/X31 (a) or anti-HKB (b) by autologous E cells, as described in Fig. 1 legend. Results are expressed as a percentage of the optimal response induced by 10° E<sup>+</sup> cells.

conceivable that these helper cells will not grow in the absence of another 'amplifier cell', also of the 3a+ phenotype.

The genetically restricted nature of the specific helper factor obtained here is intriguing, and is comparable with other results in the mouse<sup>10</sup> and with the specific nature of the help for anti-tetanus antibody production in humans<sup>16</sup>, but is in contrast to many others<sup>8,13</sup>. In view of the genetic restriction repeatedly observed in T-B collaboration, we feel that further analysis of these cell lines should elucidate the nature of T-cell receptors and their factors, and the mechanisms of T-B collaboration.

We thank Drs R. Callard and E. Zanders for their helpful advice; Mary Oliver and Dr J. Bodmer for HLA typing; Dr J. Skehel for the gift of influenza viruses; Drs M. Crumpton, G. Goldstein (Ortho Pharmaceuticals) and J. Kersey for gifts of monoclonal antisera; and Dr T. Davies of the National Blood Transfusion Centre for supplies of serum and blood cells. We thank Drs N. A. Mitchison and W. Bodmer for comments on the manuscript.

# Antibody directed at a surface structure inhibits cytolytic but not suppressor function of human T lymphocytes

Ellis L. Reinherz, Rebecca E. Hussey, Kathleen Fitzgerald, Peter Snow, Cox Terhorst & Stuart F. Schlossman

Division of Tumor Immunology and Department of Medicine, Sidney Farber Cancer Institute, Harvard Medical School, 44 Binney Street, Boston, Massachusetts 02115, USA

Experiments using conventional antisera<sup>1,2</sup> and monoclonal antibodies3-5 have shown that there are two functionally distinct human T-cell subsets which express unique cell-surface glycoproteins<sup>6-9</sup>. The inducer population expresses a 62,000molecular weight  $(M_r)$  antigen termed T4 (ref. 6) whereas the cytotoxic/suppressor population lacks T4 but expresses T5 antigen. This antigen is a 76,000-M, molecule in nonreducing conditions and a 33,000-M<sub>r</sub> glycoprotein occasionally appearing as a doublet in reducing conditions. As the functions of subset-specific T-cell surface glycoproteins have not been elucidated, we have now examined the effect on T-cell function three monoclonal antibodies reactive with the cytotoxic/suppressor subset; anti-T8, antibody markedly inhibited cell-mediated lympholysis (CML) and anti-T8 partially affected CML, whereas anti-T5 had no effect. In contrast, there was no effect on suppressor cell function. Immunoprecipitation studies and competitive binding experiments indicated that anti-T8 and anti-T8A, like anti-T5, defined a 33,000-M, antigen. Taken together, our results suggest that of a possible of  $33,000-M_r$  glycoproteins on the cytotoxic/suppressor T-lymphocyte subset, that which is reactive with anti-T8<sub>A</sub> has some effect on the cytolytic mechanism.

Effector function for CML resides in the subset of T lymphocytes recognized by the antibodies anti-T5 and anti-T8 (refs 3, 4, 9), which are monoclonal hybridoma products of IgG1 and IgG2a isotypes, respectively<sup>4,5</sup>. Elimination of the subsets of cells reactive with these antibodies by fluorescence-activated cell sorting (FACS) or, in the case of anti-T8, complementmediated lysis, was found to abrogate the cytotoxic effector function of the unfractionated T-cell population9. Here, an additional monoclonal antibody, anti-T8A, was developed by standard hybridoma techniques after immunization of a BALB/cJ mouse with human thymocytes as described previously<sup>10</sup>. Hybridoma cultures containing antibody reactive with E<sup>+</sup> or thymocyte populations or both were selected, cloned and recloned by limiting dilution methods in the presence of feeder cells. Malignant ascites were then developed and used for analysis. Anti-T8<sub>A</sub> represents an ascites from one hybridoma clone (SFCI 21Thy). The pattern of reactivity of the anti-T8<sub>A</sub> was identical to that described for anti-T8 (ref. 5) as it defined -80% of thymocyte and 30-35% of peripheral T cells and was unreactive with B cells, null cells and macrophages by indirect immunofluorescence.

To determine whether the antigens defined by these antibodies were themselves important for the cytotoxic response of T lymphocytes, the following procedure was used. T cells were sensitized to alloantigens in mixed lymphocyte culture (MLC) for 6 days. Subsequently, the cytotoxic cells (CTL) were collected, incubated with a 1:1,000 dilution of a given monoclonal antibody or control and their ability to lyse 51 Cr-labelled target cells was investigated. In the absence of monoclonal antibody (control), specific lysis in primary CML was ~28-29% at either

Table 1 Effect on % specific lysis of preincubation of CTL with monoclonal antibodies

		Specific lysis at ctor/target ratio	
Monoclonal antibody	40 · 1	20:1	10:1
Control Anti-T5 Anti-T8 Anti-T8 <sub>A</sub>	28±2 30±2 16±2 2±1	29±1 28±2 14±2 2±1	$21\pm1$ $22\pm2$ $15\pm1$ $0.7\pm1$

Peripheral T cells were activated in one-way MLC with mitomycin C-treated allogeneic, human mononuclear cells as previously described 10. Subsequently, alloantigen-activated killer cells were collected and tested in a 51 Cr microcytotoxicity assay for 4 h (ref. 3). Specificity of CML was tested by using an additional allogeneic target population unrelated to the mononuclear population used in the initial sensitization phase of MLC. The level of nonspecific killing was always <10% of specific killing. To determine whether anti-T5, anti-T8 or anti-T8<sub>A</sub> antibody inhibited CML in the absence of complement, some killer cells were incubated with a 1:1,000 dilution of monoclonal antibody or control ascites at 20 °C for 30 min before addition of the relevant target cells. The control ascites was obtained from BALB/cJ mice immunized with a non-producing hybridoma clone 10.

a 40:1 or 20:1 effector/target cell ratio but was reduced to 21% at a 10:1 effector/target ratio (see Table 1). Preincubation of cytotoxic cells with anti-T5 did not affect the magnitude of this response, whereas preincubation of 6-day MLC-stimulated cells with anti-T8 resulted in a diminished percentage specific lysis such that, even at a 40:1 effector/target cell ratio, only 16% of target cells were killed. A similar percentage lysis was obtained if the effectors were preincubated with anti-T8 and used at an effector/target ratio of 20:1 or 10:1. In contrast, the anti-T8A monoclonal antibody almost completely inhibited killing. These findings indicate that anti-T5 has no inhibitory effect on the effector phase of CML whereas the anti-T8 and anti-T8A monoclonal antibodies have a moderate to marked effect, respectively. These effects were seen at dilutions of monoclonal antibody between  $10^{-2}$  and  $10^{-4}$ . As anti-T5 and anti-T8<sub>A</sub> monoclonal antibodies are of the IgG1 subclass<sup>3</sup>, the results cannot be explained by differences in immunoglobulin isotype.

Anti-T8<sub>A</sub> had no effect on CTL effector function when added at the initiation of MLC (data not shown). In contrast, anti-T3 regularly blocked CTL generation in MLC and generally also blocked at the effector phase<sup>11-15</sup>. The observation that anti-T3, which defines a 19,000-M<sub>r</sub> glycoprotein, and anti-T8<sub>A</sub>, which defines a 33,000-M<sub>r</sub> protein, both inhibit cytolysis suggests that multiple cell surface antigens are important in mediation of CML.

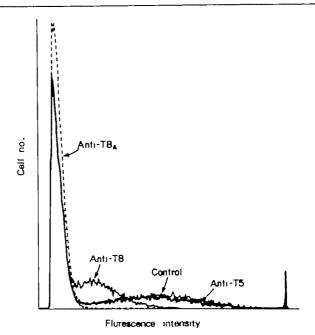

Fig. 1 Competitive blocking studies with monoclonal antibodies to cytotoxic/suppressor cells. The relationships between anti-T5, anti-T8 and anti-T8<sub>A</sub> antibodies were examined in competitive binding studies by direct immunofluorescence using FACS<sup>10</sup>. T cells (1×10<sup>5</sup>) were treated with 0.15 ml of a 1:100 dilution of either control ascites, anti-T5, anti-T8 or anti-T8<sub>A</sub>, incubated at 4 °C for 30 min and washed twice. The control ascites was obtained from BALB/cJ mice (see Table 1). The cells were reacted with 0.15 ml of a 1:50 dilution of directly fluoresceinated anti-T8<sub>A</sub> at 4 °C for 30 min, centrifuged and washed three times. Subsequently, 40,000 cells were analysed on the FACS I (Becton Dickimson) and the intensity of fluorescence per cell recorded on a pulse height analyser.

As T5(T8<sup>+</sup>) T cells have been observed to suppress pokeweed mitogen (PWM) induced immunoglobulin synthesis, we examined whether antibodies to the T5, T8 or T8<sub>A</sub> antigen could affect this suppressor function. B cells and T4<sup>+</sup> inducer T cells were cultured with various numbers of T8<sup>+</sup> T cells in the presence of the particular monoclonal antibody and stimulated with PWM. Immunoglobulin production was measured by radioimmunoassay after 7 days of culture. As expected (Table 2), T4<sup>+</sup> T cells induced B-cell immunoglobulin production whereas T8<sup>+</sup> T cells did not (11,000 as opposed to <200

Unfractionated mononuclear cells were separated into T- and B-enriched populations as previously described. The B-cell population was <1% E-rosette positive. The T4<sup>+</sup> and T8<sup>+</sup> T-cell subsets were obtained by complement-dependent lysis of unfractionated T cells with anti-T8 and anti-T4, respectively, and were ≥93% pure on re-analysis. To 5×10<sup>4</sup> B cells or final medium (RPMI 1640 supplemented with 20% heat-inactivated fetal calf serum (Microbiological Associates), 200 mM L-glutamine, 25 mM HEPES buffer (Microbiological Associates), 0.5% sodium bicarbonate and 1% penicillin-streptomycin) were added varying numbers of T4<sup>+</sup> and T8<sup>+</sup> T cells in a total volume of 0.1 ml with 0.1 ml PWM (Gibco) diluted 1:50 in final medium containing control ascites (1:100), anti-T5 (1:100), anti-T8 (1:100) or anti-T8<sub>A</sub> (1:100). After 7 days in culture at 37 °C in a humid atmosphere with 5% CO<sub>2</sub>, culture supernatants were collected and IgG secretion during the 7-day period determined by solid phase radioimmunous y.

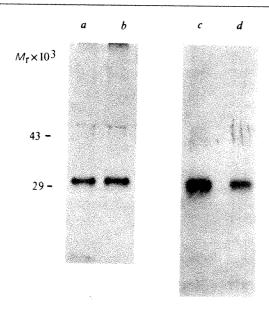

Fig. 2 Characterization and isolation of the T5, T8 and T8<sub>A</sub> antigens. The external proteins of the human T-cell line HPB-ALL were labelled with 125I using IODO-GEN (Pierce). Labelled cells washed three times with phosphate-buffered saline containing inhibitor trypsin (Sigma), 2 mM phenylmethylketonesulphone (PMKS) and 1 mM iodioacetamide (Pierce) were extracted with 1% Nonidet-P40 (NP40; Partide Data Laboratories, Elmhurst, Illinois) in 0.01 M Tris-HCl pH 8.0, 2 mM PMKS, trypsin inhibitor and 1 mM iodoacetamide at 0 °C for 30 min. Nuclear debris was removed in an Eppendorf centrifuge (15 min at 12,000g) and the supernatant cleared in an Airfuge (30 min at 100,000g; Beckman). Immunoprecipitations were carried out by a technique which uses preformed complexes prepared from rabbit anti-mouse IgG serum and the monoclonal reagent anti-T5, anti-T8 or anti-T8<sub>A</sub> as described elsewhere<sup>6</sup>. Immunoprecipitates were washed with 0.01 M Tris-HCl pH 8.0, 0.59% deoxycholate, 2 mM PMKS and 0.01 M Tris-HCl pH 8.0, 0.2% NP40. The surface antigens immunoprecipitated with the anti-T5, anti-T8 and anti-T8<sub>A</sub> monoclonal antibodies were analysed by SDS-polyacrylamide gel electrophoresis on 5-15% gradient gels. a, Anti-T8; b, anti-T8<sub>A</sub>; c, anti-T8; d, anti-T5.

ng ml<sup>-1</sup>, respectively, secreted over 7 days). Furthermore, when increasing numbers of T8+ T cells were added to a mixture of  $2 \times 10^4 \,\mathrm{T}^{4+} \,\mathrm{T}$  cells and  $5 \times 10^4 \,\mathrm{B}$  cells, immunoglobulin production was markedly suppressed. When  $5 \times 10^4 \text{ T8}^+\text{ T}$  cells were added to the T4+B cell mixture, immunoglobulin production decreased by >50% to 4,000 ng. IgG secretion was virtually abolished (300 ng ml<sup>-1</sup>) when  $1\times10^5$  T8<sup>+</sup> T cells were added to the T4<sup>+</sup>-B cell population. More importantly, preincubation of the mixture of T and B cells with anti-T5, anti-T8 or anti-T8A had no effect on the suppression caused by the T8<sup>+</sup> T-cell subset. Thus, it seems that the inhibitory effect of anti-T8<sub>A</sub> is selective for cytotoxic effector, rather than suppressor, function. However, the two assays are not comparable as the former occurs over 4 h and the latter over 7 days.

To determine whether these monoclonal antibodies defined related or distinct sets of antigens, the ability of one monoclonal antibody to inhibit binding of a second was determined by direct immunofluorescence. As shown in Fig. 1, ~30% of peripheral T cells were reactive with fluorescein isothiocyanate-conjugated (FITC)-labelled anti-T8<sub>A</sub> in a FACS. Preincubation of T cells with unlabelled anti-T8<sub>A</sub> before addition of FITC-anti-T8<sub>A</sub> totally inhibited the binding of the latter. In contrast, preincubation with unlabelled anti-T5 was not inhibitory. Preincubation of T cells with anti-T8 antibody showed a partial inhibition of FITC-anti-T8<sub>A</sub> binding. Similarly, preincubation of T cells with anti-T8<sub>A</sub> inhibited binding of FITC-anti-T8. These results suggest that the determinant defined by anti-T5 is

distinct from that defined by anti-T8<sub>A</sub> and that anti-T8 and anti-T8A seem to react with a related structure.

The molecular nature of these antigens was then examined in a second series of experiments. Solubilized membrane preparations were obtained from the externally labelled human T-cell line HPB-ALL and the antigens defined by anti-T5, anti-T8 and anti-T8<sub>A</sub> antibodies precipitated and electrophoresed on SDS-polyacrylamide gels. As previously reported<sup>6</sup>, the antigen precipitated by anti-T5 antibody was a 33,000-M<sub>r</sub> protein in reducing conditions (Fig. 2) and a 76,000 M<sub>r</sub> protein in non-reducing conditions (data not shown). The anti-T8 and anti-T8A antibodies precipitated molecules of the same molecular weight (Fig. 2). Although these antigens appear similar and, in sequential precipitation studies anti-T8<sub>A</sub> largely removed both the T8A and T8 antigens, anti-T5 did not deplete T8 antigen (data not shown). These results suggest that the T5 and T8 antigens are not identical. A similar conclusion was reached after analysis of T-ALL tumour cells using anti T5 and anti-T8 in which some cell were reactive with anti-T8 but unreactive with anti-T5 (ref. 5).

Both the biochemical data and binding studies are consistent with the view that the T8 and T8<sub>A</sub> epitopes are located close together on a single molecule. However, proof of this conclusion must await peptide mapping and two-dimensional gel analysis. Nevertheless, the inhibition of CTL function implies that the epitope defined by anti-T8<sub>A</sub> may be critical for cytolytic function but not for suppressor function. Thus, these antigens seem to be homologous to Lyt2, which has been shown to inhibit murine CTL to varying degrees<sup>16,17</sup>. A recent report<sup>18</sup> suggests that another antibody defining the human cytotoxic cell population, termed anti-Leu2a, blocks CML. It is possible that this antibody may be directed against the same  $33,000-M_r$  protein.

The ability of anti-T8<sub>A</sub> to inhibit CML at the effector phase may involve blocking of structures near or associated with the antigen receptor of the T cell. Alternatively, Lyt2 or T8A may serve as molecules permitting attachment for conjugate formation between killer and target cells without themselves being antigen-specific receptors 19. Further experiments using purified and reconstituted T8A antigens will help to resolve these issues.

We thank Mr John Daley for FITC conjugation of monoclonal antibodies and technical assistance with the FACS. This work was supported by NIH research grants AI 12069, CA 19589 and CA 06516, and a grant from the National Multiple Sclerosis Society RG 1359-A1.

# Anti-transferrin receptor monoclonal antibody and toxin-antibody conjugates affect growth of human tumour cells

#### Ian S. Trowbridge & Derrick L. Domingo

Department of Cancer Biology, The Salk Institute for Biological Studies, PO Box 85800, San Diego, California 92138, USA

The development of the monoclonal antibody technique has led to renewed interest in whether the growth of tumour cells may be specifically inhibited by antibodies or antibody-toxin conjugates directed against antigenic determinants selectively expressed on tumour cells2-10. We have recently obtained monoclonal antibodies against the transferrin receptor of human cells<sup>11,12</sup>, which is thought to have an essential role in transport of Fe across the cell membrane and which is selectively expressed on proliferating cells in vivo and in vitro 13-17. In some cases, transferrin receptors can be used as a marker to distinguish between tumour cells and normal tissue 11,15-17. Here we show that human tumour cells are specifically killed in vitro by anti-transferrin receptor antibody covalently coupled to ricin or diphtheria toxic subunits. In experiments designed to test the effectiveness of these antibody-toxin conjugates in vivo, we found that anti-transferrin receptor antibody alone inhibits the growth of human melanoma cells in nude mice.

The mouse monoclonal IgG1  $\kappa$  antibody against the human transferrin receptor, designated B3/25, has been described previously<sup>11,12</sup>. The antibody was purified from ascitic fluid of tumour-bearing mice by precipitating with ammonium sulphate and fractionation on DEAE-cellulose. Ricin A toxic subunit was prepared from affinity-purified ricin toxin by reduction with 2-mercaptoethanol and fractionation on DEAE- and is. Diphtheria fragment A was prepared from CM-cellulose<sup>1</sup> diphtheria toxin (Connaught Laboratories) by tryptic cleavage<sup>1</sup> followed by reduction with 2-mercaptoethanol and chromatography on Sephacryl S-200. Antibody-toxin conjugates were N-succinimidyl-3-(2-pyridyldithio)synthesized using propionate (SPDP; Pharmacia)20. A sixfold molar excess of SPDP was used to introduce an average of three 2-pyridyldisulphide groups into the anti-receptor antibody. The modified antibody was then mixed with a threefold molar excess of freshly reduced ricin A subunit or diphtheria fragment A and incubated at 4°C for 36 h. The antibody conjugate was purified from unbound toxin subunits by chromatography on Sephacryl S-200. On average, 1-2 toxin subunits were covalently bound to each antibody molecule.

The effect of anti-transferrin receptor antibody-ricin A conjugate on protein synthesis in a human T leukaemic cell line, CCRF-CEM<sup>21</sup>, is shown in Fig. 1. It can be seen that the antibody-ricin A conjugates inhibit protein synthesis almost as effectively as the intact toxin. The residual protein synthesis in cells treated with high concentrations of the conjugate reflects the fact that the conjugate seems to act less rapidly than the intact toxin and is not observed if cells are exposed to the conjugate for 48 h. It is possible that cells differ in susceptibility to the antibody-ricin A conjugate depending on their position in the cell cycle. Antibody or ricin A subunit added alone or as a mixture, inhibited protein synthesis only at concentrations 200-1,000-fold higher than the antibody-ricin A conjugate. The specificity of the antibody-ricin A conjugates is further indicated by the fact that protein synthesis in a mouse lymphoma cell line, BW5147, was not inhibited by the anti-human transferrin receptor antibody-ricin A conjugate even though the cells were as sensitive as CCRF-CEM cells to the intact ricin toxin (Table 1). Specific inhibition of protein synthesis in CCRF-

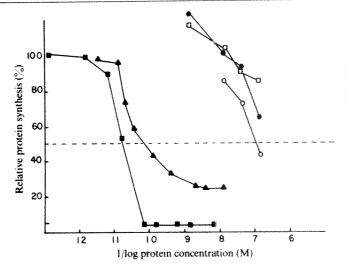

Fig. 1 Protein synthesis in a human leukaemic cell line is inhibited by anti-transferrin receptor-ricin A conjugate. CCRF-CEM cells (1×10<sup>6</sup>) were cultured for 20 h in 2.0 ml RPM1 1640 medium supplemented with 10% horse serum and various concentrations of ricin toxin (■), anti-transferrin receptor plus ricin A conjugate (Δ), ricin A subunit (Φ), anti-transferrin receptor antibody (□), or anti-transferring receptor antibody plus ricin A subunit (○). Then 10 μCi of <sup>3</sup>H-leucine (42 Ci mmol<sup>-1</sup>, NEN) were added to each dish and the cells were incubated for 2 h. Cells from duplicate cultures for each treatment were collected and incorporation of radioactivity into trichloroacetic acid-insoluble material was determined. Protein synthesis in treated cells was expressed as a percentage of <sup>3</sup>H-leucine incorporation into untreated control cells. Note that although ricin A was diluted in this experiment from a stock solution at 250 μg ml<sup>-1</sup> in 0.1% mercaptoethanol, in earlier experiments dialysis was carried out to remove the reducing agents without increasing the toxicity of the free ricin A chain.

CEM cells was also obtained with an anti-receptor antibody-diphtheria fragment A conjugate. Protein synthesis in HeLa cells and cells of a human melanoma cell line  $(M21)^{22}$ , was inhibited by anti-receptor antibody-ricin A, although M21 cells seemed less sensitive than CCRF-CEM cells.

As a further test of the ability of the anti-receptor antibodyricin A conjugate to kill tumour cells in vitro, and to assess the frequency with which cells might escape killing, we performed cloning assays. CCRF-CEM cells were plated out in twofold dilutions at concentrations ranging from  $5-1\times10^6$  cells per ml in 0.2 ml tissue culture medium in microtitue wells. No growth was observed even in wells containing  $2\times10^5$  cells in the presence of anti-receptor-ricin A antibody (10 nM), whereas a cloning efficiency of  $\sim30\%$  was observed in the absence of the con-

Table 1 Inhibition of protein synthesis in human tumour cell lines by anti-transferrin receptor-toxic subunit conjugates

Cell line	•	IC <sub>50</sub> Antibody-ricin A	Ricin toxin alone
CCRF-CEM human T leukaemia	1.5	0.06, 0.04, 0.09, 0.03*, 0.06*	0.03
M21 human melanoma	integration.	3.5	Suddistractions
HeLa	-	0.25	antimphoto
BW5147 mouse lymphoma	>11	> 13	0.04

The concentration (nM) required for 50% inhibition of protein synthesis (IC<sub>50</sub>) was calculated from results obtained in experiments of the type shown in Fig. 1. The same preparation of ricin A-antibody conjugate was used for all experiments, except for the two IC<sub>50</sub> values for CCRF-CEM cells marked with an asterisk: a separate preparation of conjugate was used in these two experiments.

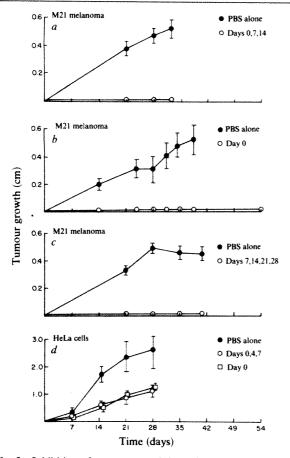

Fig. 2 Inhibition of tumour growth in nude mice by anti-transferrin receptor monoclonal antibody. Groups of BALB/c (nu/nu) mice (4 mice per group, females 4-5 weeks old) were given subcutaneous inoculations of 2×10<sup>7</sup> M21 melanoma or HeLa cells. Anti-transferrin receptor monoclonal antibody or antibodyricin A conjugate was then given i.v. in 0.2 ml phosphate-buffered saline (PBS) either immediately (day 0) or at the times indicated (open symbols). In a, 50 μg of ricin A-antibody conjugate was injected each time. For experiments b-d, 880 µg of unmodified antibody was given on each occasion. Control mice were injected with PBS alone (solid symbols). Tumour growth was estimated by measuring two perpendicular diameters of the tumours using calipers; results are expressed as geometric mean ± 1 s.e.

jugate. In similar experiments, no survivors were obtained when  $2 \times 10^5$  HeLa cells were treated with the same concentration of the antibody conjugate. In contrast, no effect was observed on the cloning efficiency of BW5147 mouse lymphoma cells

As the antibody-toxic subunit conjugates were effective in killing human tumour cells in vitro, we set out to determine whether the antibody-ricin A conjugates were effective in inhibiting the growth of human tumour cells in nude mice. As CCRF-CEM cells do not produce tumours in nude mice, M21 and HeLa cells were used. We found that the antibody-ricin A conjugate (50 µg intravenously (i.v.) on days 0, 7, 14) completely inhibited the growth of M21 cells in nude mice (Fig. 2a). However, a single i.v. injection of 880 µg of anti-transferrin receptor antibody alone also inhibited the growth of the melanoma cells at a subcutaneous site (Fig. 2b). The same results have been obtained in four similar experiments. In a fifth experiment, tumour formation was delayed but not completely inhibited. As shown in Fig. 2c, administration of antibody 7 days after inoculation of tumour cells was also effective in preventing tumour growth. However, the monoclonal anti-transferrin receptor antibody was much less effective in inhibiting growth of HeLa cells in nude mice even when repeated doses of antibody were given (Fig. 2d).

In another experiment, groups of mice were given a single i.v. injection at day 0 of either 10 or 50 µg of antibody or antibodyricin A conjugate. Mice given the higher dose of either unmodified antibody or conjugate did not develop tumours, whereas tumour growth in those mice receiving lower concentrations of each reagent was not significantly different from that of the controls. Thus, there is no evidence that the conjugate is more effective than unmodified antibody in inhibiting growth of the M21 melanoma cells in nude mice. However, this may reflect instability of the antibody-ricin A conjugate in vivo, or differences in the relative clearance of unmodified and conjugated antibody from the circulation, and requires further study. Furthermore, although the antibody-ricin A conjugate inhibits growth of HeLa cells in vitro, it is no more effective than antibody alone in preventing the growth of HeLa cell tumours in nude mice.

Recent reports have indicated that specific killing of tumour cells can be achieved in vitro with antibody-toxin conjugates<sup>2-5,7</sup>. We have shown here that similar results can be obtained with anti-human transferrin receptor antibodies coupled to ricin A subunit or diphtheria fragment A. More importantly, we have shown that growth of a human melanoma cell line in nude mice can be effectively inhibited by anti-human transferrin receptor antibody alone. In contrast, previous attempts to inhibit growth of murine lymphomas by administration of either anti-Thy-1 antibody<sup>5</sup> or ricin A-anti-Thy-1 antibody conjugates7 were only partially effective. Whether inhibition of M21 tumour growth is due to immunological mechanisms or to the effect of antibody on the ability of the tumour cells to compete for Fe in vivo remains to be determined. Clearly, however, sufficient antibody to inhibit growth can be delivered to the subcutaneous tumour by an i.v. injection. Furthermore, it seems that in vitro tests are of limited value in predicting the in vivo effects of antibody reagents on tumour growth.

Our preliminary results and the known properties of the transferrin receptor suggest that further studies of the usefulness of anti-receptor antibodies as therapeutic agents would be worthwhile. The transferrin receptor is a major glycoprotein on dividing tumour cells and is not rapidly shed from the cell surface (M. B. Omary and I. S. T., unpublished results). It is probably essential for cell growth, thus it is unlikely that tumour cells would be able to escape killing either by antigenic modulation<sup>23</sup> or by genetic loss of receptors<sup>24</sup>. As it is thought that receptor-bound transferrin is internalized<sup>25,26</sup>, the transferrin receptor might be expected to facilitate entry of bound antibody conjugates into the cell. Furthermore, anti-receptor antibodies may exert inhibitory effects on growth by interfering with Fe transport. Finally, as transferrin receptors are known to be present on mouse tumour cells, suitable animal models can be used to test the effectiveness of anti-receptor monoclonal antibody on in vivo growth of transplanted and spontaneous tumours and to examine the potential deleterious effects of antibody on normal dividing cells. A rat monoclonal antibody to the mouse transferrin receptor has recently been obtained (I.S.T., J. Lesley and R. Schulte, unpublished results).

Although the transferrin receptor is obviously not a tumourspecific antigen, there is little evidence that such antigens exist in man, and careful studies have always revealed that putative tumour-specific antigens are expressed on some normal cells<sup>27-29</sup>. Indeed, the transferrin receptor itself may be the putative cell surface glycoprotein associated with malignancy described elsewhere 30,31. Given this situation, it is probable that absolute specificity of anti-tumour antibody reagents is unlikely to be achieved. However, sufficient specificity may be obtained using monoclonal antibodies against target antigens such as the transferrin receptor, alone or in combination, to be of practical therapeutic importance.

## Assignment of the genes for human λ immunoglobulin chains to chromosome 22

#### Jan Erikson, Joanne Martinis\* & Carlo M. Croce

The Wistar Institue of Anatomy and Biology, 36th and Spruce Streets, Philadelphia, Pennsylvania 19104, USA

Human immunoglobulin chains are expressed in somatic cell hybrids between mouse myeloma cells and human B cells<sup>1,2</sup>. By correlating the expression of human immunoglobulin chains and the presence of specific human chromosomes in the hybrid clones, we have assigned the human immunoglobulin heavychain gene cluster to human chromosome 14 (refs 1, 2). We have now studied somatic cell hybrids between mouse myeloma cells and either human peripheral lymphocytes or different human A chain-secreting lymphoblastoid cell lines. Somatic cell hybrid clones were pre-selected for their ability to produce human A immunoglobulin chains, and studied for the expression of isozyme markers assigned to each of the different human chromosomes. Subclones of human A chain-secreting hybrid clones were also studied. The results indicate that human chromosome 22 carries the human  $\lambda$  immunoglobulin chain genes.

We fused hypoxanthine phosphoribosyltransferase (HPRT)deficient P3×63Ag8 mouse myeloma cells<sup>3</sup> with either peripheral blood lymphocytes or different human lymphoblastoid cells (GM1056 that secretes IgA  $\alpha$ 2,  $\lambda$ ; GM923 that secretes IgA  $\alpha 1$ ,  $\lambda$ )<sup>4</sup> to map the chromosomal location of the human λ-chain genes. The hybrids were selected either in hypoxanthine-aminopterin-thymidine (HAT) medium or in HAT medium containing 10<sup>-4</sup> M ouabain<sup>1,2</sup>. After selection the hybrids were cloned in non-selective medium; each clone derived from an independent hybrid colony. As only one of the alleles for the different immunoglobulin chains is expressed in immunoglobulin-producing cells, the other being silent ('allelic exclusion')5, we can predict the presence of hybrids that have retained the chromosomes carrying immunoglobulin chain genes, but do not express them. In fact, we have shown previously that only a fraction of mouse × human hybridomas containing human chromosome 14 expresses human heavy chains<sup>1,2</sup>. Recently, by using  $\mu$  chain-specific cDNA probes<sup>4</sup> and Southern blotting procedures<sup>6</sup>, we have confirmed assignment

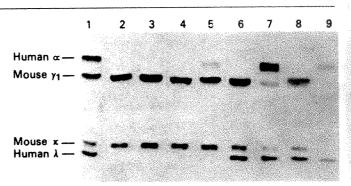

Fig. 1 SDS-polyacrylamide gel electrophoresis of immunoglobulin chains secreted by somatic cell hybrids between P3 × 63Ag8 mouse myeloma cells<sup>3</sup> and GM1056 human lymphoblastoid cells<sup>4</sup>. Parent and hybrid cells were grown for 24 h in leucine-deficient media containing 100 μCi ml<sup>-1</sup> <sup>3</sup>H-leucine (70 Ci mmol<sup>-1</sup>). Cells were pelleted and supernatants (500 μl) reacted with 25 μl of rabbit anti-human λ chain-specific sera and rabbit anti-mouse immunoglobulins for 1 h in ice. 100 µl of a 10% suspension of fixed Staphylococcus aureus 1.2 were added to each reaction mixture for 30 min, or 50  $\mu$ l of goat anti-rabbit  $\gamma$ -globulin sera were added for 16–18 h, at 4°C. Double antibody precipitates were collected by centrifugation through a pad of 0.2 ml 1 M sucrose. All immuse precipitates were washed with 5% sucrose, 15 mM Tris-HCl pH 7.4, 0.5 M NaCl, 5 mM EDTA, 1% NP-40, 2 mM phenylmethylsulphonyl fluoride. The immune precipitates were resuspended in Laemmli buffer17 and analysed on 10-11% polyacrylamide gels<sup>17</sup>, embedded in 2,5-diphenyloxazole and subjected to fluorography<sup>18</sup> for 5-14 days. Lanes 2 and 9 show the immunoprecipitates of the culture fluids of P3×63Ag8 and GM1056 respectively. GM1056 cells secrete IgA ( $\alpha 2$ ,  $\lambda$ ). The  $\lambda$  chain produced by these cells migrates faster than the mouse  $\kappa$  and the human  $\lambda$  chains produced by independent hybrid clones between P3  $\times$  63Ag8 cells and human peripheral lymphocytes (see Figs 2, 3). In lanes 1, 3-8 are the immunoprecipitates of P3  $\times$  63Ag8  $\times$  GM1056 hybrids: human  $\alpha$  and  $\lambda$  chains segregate independently in these hybrids. Immunoprecipitation of cytoplasmic immunoglobulin chains 1.2 present in the hybrids was also carried out, with identical results (data not shown).

of the human heavy-chain genes to human chromosome 14 (T. Dolby, A. Dayton and C. M. C., in preparation). Because of allelic exclusion<sup>5</sup> we decided to pre-select mouse×human hybridomas for the expression of human  $\lambda$  chains (Figs 1, 2) and to study the  $\lambda$  chain-producing hybrids for the expression of isozyme markers assigned to each of the different human chromosomes. The independent hybrid clones segregated into  $\lambda$ chain-secreting and non-secreting hybrids (Fig. 1). As the parental mouse myeloma cells were secreting immunoglobulins. each of the hybrids producing a human immunoglobulin chain was also secreting it1,2.

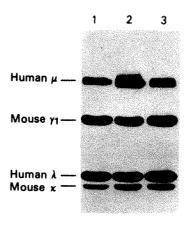

Fig. 2 SDS-polyacrylamide gel electrophoresis of immunoglobulin chains secreted by somatic cell hybrids between P3× 63Ag8 mouse myeloma cells<sup>3</sup> and human peripheral blood lymphocytes. The human and mouse immunoglobulin chains were labelled and immunoprecipitated as described in Fig. 1 legend. The independent hybrids (lanes 1-3), pre-selected for isozyme analysis, were expressing human A chain. Immunoprecipitation of cytoplasmic immunoglobulin chains present in the hybrids was also carried out, with identical results (data not shown).

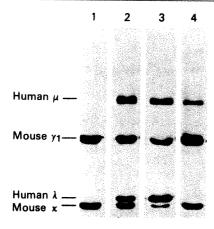

Fig. 3 SDS-polyacrylamide gel electrophoresis of immunoglobulin chains secreted by four hybrid subclones of a hybrid clone between P3×63Ag8 cells and human peripheral blood lymphocytes (see Fig. 2). The expression of the human  $\mu$  and  $\lambda$  chains segregated independently in the hybrid subclones. The subclones in lane 1 have lost the ability to secrete (produce) human  $\mu$  and  $\lambda$ chains, whereas those in lanes 2 and 3 have retained the expression of these chains. The subclones in lane 4 have lost the ability to secrete (produce) human  $\lambda$  chains. Immunoprecipitation of cytoplasmic immunoglobulin chains present in the hybrids was also carried out, with identical results (data not shown).

Table 1 shows that only human chromosomes 14 and 22 are likely to carry the human  $\lambda$  heavy-chain genes, as hybrid clones lacking each one of the other human chromosomes were found to produce human  $\lambda$  chains. As the genes for heavy,  $\kappa$  and  $\lambda$  immunoglobulin chains lie on different chromosomes 1.2.7.8, and

as the heavy-chain genes are located on human chromosome 14 (refs 1, 2), human chromosome 22 is the likely candidate for carrying the human λ-chain genes. All 20 independent hybrid clones tested for nucleoside phosphorylase (a marker of human chromosome 14) were positive for the enzyme as this chromosome is preferentially retained in mouse × human hybridomas<sup>9</sup>. To exclude the possibility that the human  $\lambda$ -chain genes are located on human chromosome 14 and to confirm their assignment to human chromosome 22, we subcloned five independent  $\lambda$  chain-secreting (producing) clones, and studied them for expression of human  $\lambda$  chains (Fig. 3) and of isozyme markers assigned to each of the different human chromosomes. As shown in Table 2, chromosome 14 can be excluded from consideration as two subclones have lost chromosome 14 yet have retained the ability to produce human  $\lambda$  chains. In addition, the results confirm that the genes for  $\lambda$  chains are on human chromosome 22, as this is the only human chromosome consistently present in all subclones secreting human  $\lambda$  chains (Table 2, 2nd column). Loss of human chromosome 22 results in loss of the ability to produce human  $\lambda$  chains (Table 2, 4th column and Fig. 3, lane 4).

Our results parallel those obtained by Southern blotting analysis of hybrid cell DNAs using nucleic acid hybridization probes (W. McBride and P. Leder, personal communication). These findings, in conjunction with the assignment of the heavychain gene clusters to human chromosome 14 (refs 1, 2) and of the human k-chain gene to human chromosome 2 (W. McBride and P. Leder, personal communication), suggest a possible relationship between specific chromosome translocations, immunoglobulin genes and the expression of malignancy in Burkitt's lymphoma<sup>10</sup>. A translocation between chromosomes 8 and 14, described as t (8, 14) (q24; q32), has been found in numerous cases of the disease<sup>11,12</sup>. Recently, two different translocations involving human chromosome 8 have been described in non-African Burkitt's lymphoma13-15, which involve the same segment of human chromosome 8 and either human chromosome 22 (that carries the  $\lambda$ -chain genes) or chromosome 2 (that carries the  $\kappa$ -chain gene). More recently, similar translocations, t (2, 8) (p12; q24) and t (8, 22) (q24; q11), have also been found in cases of African Burkitt's lymphoma<sup>1</sup> These findings indicate that approximately the same segment of human chromosome 8 is translocated to each of the human chromosomes carrying immunoglobulin genes in Burkitt's lymphoma. It would be interesting to determine whether the

break points on human chromosomes 2, 14 and 22 affect chromosomal DNA segments that lie close to or contain the human immunoglobulin chain genes.

# Phaseolin mRNA is translated to vield glycosylated polypeptides in Xenopus oocytes

Jayne A. Matthews, John W. S. Brown\* & Timothy C. Hall

Department of Horticulture, University of Wisconsin, Madison, Wisconsin 53706, USA

The cotyledons of developing bean (Phaseolus vulgaris L.) seeds rapidly synthesize and accumulate the storage globulin, phaseolin1, which seems to be encoded as a small multigene family<sup>2,3</sup>. Phaseolin from the cultivar 'Tendergreen' has been resolved electrophoretically into three components (of differing molecular weights), designated  $\alpha$  (51,000),  $\beta$  (48,000) and  $\gamma$ (45,500). The in vitro synthesis of phaseolin has been investigated previously using a cell-free translation system derived from wheat germ<sup>4</sup>. The *in vitro* products did not co-migrate with the authentic polypeptides, the differences apparently being due to the lack of glycosylation of the primary transcripts. We have now used Xenopus oocytes to translate mRNA from bean cotyledons and find that phaseolin is synthesized in a glycosylated form very similar to authentic phaseolin and is transported into the membrane fraction of the cells.

Translation of bean cotyledon mRNA in cell-free extracts from wheat germ4 yielded polypeptide products that were immunoprecipitated by phaseolin-specific antibodies and which gave peptide maps, using the Cleveland procedure5, similar to those of authentic protein<sup>6</sup>. However, SDS-polyacrylamide gel electrophoresis (PAGE) of the in vitro products resolved only two bands that migrated close to, but slightly faster than, the positions of the  $\beta$  and  $\gamma$  bands of the native protein<sup>4</sup>. It has previously been suggested that these two bands represent unglycosylated forms of phaseolin, the lower band consisting of co-migrating, unprocessed forms of the  $\beta$  and  $\gamma$  polypeptides and the upper band consisting of unprocessed  $\alpha$  polypeptides. This hypothesis is consistent with the different degrees of glycosylation of the  $\alpha$ ,  $\beta$  and  $\gamma$  polypeptides (3:3:1 ratio of sugar content respectively)7.

We have now investigated the hypothesis further by injecting phaseolin mRNA into the cytoplasm of Xenopus laevis oocytes and then analysing the translation products of the phaseolin mRNA by one-dimensional SDS-PAGE (Fig. 1). Three major polypeptides were immunoprecipitated with antibody prepared against phaseolin and these migrated at positions closely approximating those of authentic phaseolin (Fig. 1, lane c). In some preparations (Fig. 1, lane k), the  $\beta$  component separated into a closely migrating doublet, possibly representing slight differences in the processing of these polypeptides. The smallest component of the oocyte products migrates with a higher molecular weight (46,500) than that of the authentic protein (45,500). When the glycosylation inhibitor tunicamycin<sup>8</sup> was co-injected with phaseolin mRNA (Fig. 1, lane h), only two immunoprecipitable products were resolved. These co-migrate with the polypeptides synthesized in vitro by wheat-germ extracts in the presence of phaseolin mRNA (Fig. 1, lane a). This effect was seen most clearly when glycosylation intermediates (dolichol phosphate) were depleted by incubation of

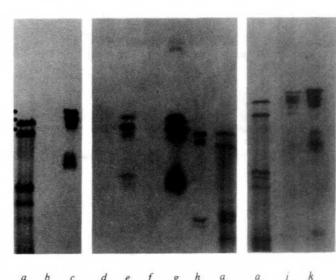

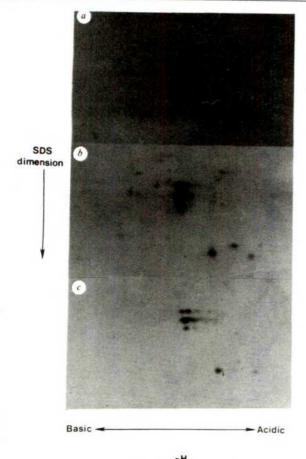

Fig. 1 Oocytes were removed from the toad and maintained in modified Barth's solution 15 at 19 °C. Phaseolin mRNA was isolated and translated in the wheat-germ cell-free system4. Phaseolin mRNA (20 ng) was injected into isolated oocytes. To study glycosylation inhibition, tunicamycin (40  $\mu g \, ml^{-1}$ ) was co-injected with the mRNA, and for such experiments, tunicamycin  $(2 \mu g \text{ ml}^{-1})$  was included in the culture medium. Unless otherwise stated, after 24 h incubation, the oocytes were placed in medium containing 2 mCi ml<sup>-1</sup> <sup>3</sup>H-leucine for a further 24 h. The radiolabelled oocytes were homogenized in 20 mM sodium phosphate pH 7.2, containing 0.5 M NaCl, 1% Nonidet P40 and 1 mM phenylmethylsulphonyl fluoride (40 µl per oocyte). Yolk and pigment were pelleted for 2 min in a microfuge. The homogenate was either analysed directly by SDS-PAGE or immunoprecipitated as described by Sun *et al.*<sup>1</sup>. For subcellular localization studies, oocytes were treated as described elsewhere<sup>8</sup>. The figure shows fluorographs<sup>16</sup> of products separated by SDS-PAGE. The lanes represent: a, total products synthesized in wheat germ in response to phaseolin mRNA; b, immunoprecipitate of mockinjected oocytes; c and k, immunoprecipitate of oocytes injected with phaseolin mRNA; d, immunoprecipitate of the cytosol fraction of oocytes injected with buffer only; e, immunoprecipitate of the cytosol fraction of oocytes injected with phaseolin mRNA; f, as d, membrane fraction of an equivalent amount of oocytes; g, as e, membrane fraction of an equivalent amount of oocytes; h, immunoprecipitate of oocytes co-injected with phaseolin mRNA and tunicamycin and placed in medium containing radioactive amino acids after 24 h incubation; and j, as h, except that injected oocytes were placed immediately in radiolabelled medium. Represents the position of stained authentic phaseolin run in the adjacent lane. The specificity of the immunoprecipitation reaction has been demonstrated previously, using the translation products of brome mosaic virus RNA as a control1

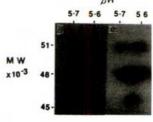

Fig. 2 Oocyte products, prepared as described in Fig. 1 legend, were separated by two-dimensional gel electrophoresis9. a Shows the separation of labelled proteins from mock-injected oocytes; b shows a similar separation of proteins from oocytes injected with phaseolin mRNA. The proteins in c are immunoprecipitates of those in b and are shown, enlarged, in e. d Shows a two-dimensional separation of authentic phaseolin of the cultivar 'Tendergreen'.

the injected oocytes for 24 h before the addition of radioactive amino acids to the medium (Fig. 1, lane h). However, when oocytes injected with phaseolin mRNA and tunicamycin were immediately placed in medium containing 3H-leucine, both glycosylated and unglycosylated forms of phaseolin were resolved (Fig. 1, lane j).

Two-dimensional separation<sup>9,10</sup> of phaseolin polypeptides synthesized in oocytes revealed that they co-migrated precisely with authentic protein in the isoelectric focusing dimension, the α component separating into two charge isomers. In the SDS-PAGE dimension, the y component migrates slightly more slowly than the authentic component (Fig. 2). The lower molecular weight components visible in the immunoprecipitate are probably the globulin-2/albumin proteins of P. vulgaris<sup>11</sup>. The mRNA preparation codes for these proteins in addition to phaseolin and the antiserum shows some reactivity with them. The identity of the minor high molecular weight products visible in the immunoprecipitates is unknown.

Phaseolin is transported across the endoplasmic reticulum of bean cotyledon cells before its accumulation in the protein

storage bodies1,12. Comparison of polypeptides accumulating in the cytosol (Fig. 1, lane e) and membrane fractions (Fig. 1, lane g) of the oocytes revealed that the bulk of phaseolin was localized in the membrane fraction. The polypeptides present in the cytosol may represent contamination during the isolation procedure; glycosylation probably occurs in the cytosol8.

Therefore, phaseolin is synthesized in oocytes as a glycosylated form which virtually co-migrates with authentic phaseolin. The slight difference in size of the  $\gamma$  band may be explained by the fact that, although oocytes can glycosylate primary translation products at the correct site<sup>13</sup>, the attached sugar moiety may not be identical with that attached in the bean cell. Phaseolin is associated with the membrane fraction of oocytes. The storage proteins of corn (zein) have also been synthesized in oocytes in membrane fractions reminiscent of protein bodies14 Such observations suggest that these proteins carry signals intrinsic to the formation of the storage organelles characteristic of many proteinacious seeds. Zein is not glycosylated but is processed by cleavage of a signal sequence 14. The results reported here argue against the involvement of signal sequence cleavage during the processing of phaseolin because the products synthesized in the presence of tunicamycin, which inhibits glycosylation but does not interfere with sequence cleavage, are the same size as those synthesized in wheat germ. Xenopus oocytes are, therefore, a valuable tool with which to investigate the processing of phaseolin.

# An 'internal' signal sequence directs secretion and processing of proinsulin in bacteria

#### Karen Talmadge, Jürgen Brosius & Walter Gilbert

Department of Biochemistry and Molecular Biology, Harvard University, Cambridge, Massachusetts 02138, USA

Most secreted proteins, both eukaryotic and prokaryotic, contain an amino-terminal extension that is removed some time during transport (see ref. 1 for a review). The signal states that these amino-terminal extensions (presequences or signal sequences) serve to bind the protein to the membrane and then to lead the protein through. We recently constructed a series of plasmids in which parts of the Escherichia coli prepenicillinase signal sequence4 were contiguous with the gene for rat preproinsulin, containing 21 of the 24 codons that code for the preproinsulin signal sequence. When Escherichia coli was transformed with each of these hybrid signal sequence constructions, an insulin antigen was secreted5 and correctly

processed to proinsulin6 in every case. One of these coustructions fused the first half of the prepenicillinase signal sequence codons to the preproinsulin gene; as insulin antigen was not secreted when the same codons were fused to the DNA coding only for proinsulin and hence lacking the eukaryotic signal sequence, we hypothesized that the enkaryotic signal sequence was sufficient to direct transport in bacteria. We could not, however, eliminate some minor but specific role for the amino terminus donated by the bacterial signal sequence. One way to do this is to replace the prepenicillinase sequences with that of a nonsecreted E, coll protein, for example  $\beta$ -galactosidase. We show here that E. coll harbouring a plasmid encoding a  $\beta$ -galactosidase-preproinsulin fusion protein efficiently secretes insulin antigen and processes the protein to proinsulin despite the fact that the signal sequence is internal to the amino terminus.

The plasmid pExlac1507 is a derivative of pBR3228 with a lac fragment inserted such that unique EcoRI and HindIII sites directly follow the first eight codons of  $\beta$ -galactosidase and the lac UV5 promoter. A PstI-terminated cDNA copy of the gene for rat preproinsulin (lacking the first three preproinsulin codons) was inserted into the *HindIII* site of pExlac150 by first removing the 3'-end overhang with the Klenow fragment of E. coli DNA polymerase I, then ligating HindIII linkers to the blunt ends, cutting with HindIII and ligating the fragment to HindIII-cut pExlac150. Figure 1 shows the DNA sequence across the region of interest on this construction, called plac 1947, from the fMet codon of  $\beta$ -galactoridase to the fourth codon of the preproinsulin gene insert (which is the seventh codon of the true preproinsulin gene). There are 18 non-signal sequence amino acids at the amino terminus before the first signal sequence amino acid: 8 are encoded by the first 8 codons of the  $\beta$ -galactosidase gene, 5 by the inserted EcoRI-HindIIIlinker, and 5 by the poly-GC tails of the cDNA insert

plac1947 transformed into E. coli K-12 strain PR13 was grown in sulphur-deficient medium, with two control constructions in the same E. coli strain. These were p241.1947, which encodes preproinsulin and where more than 90% of the insulin antigen is secreted into the periplasmic space, and p241.CB15, which lacks a signal sequence hydrophobic core and where more than 90% of the insulin antigen remains inside the cell, as determined by radioimmunoassay and reported in detail elsewhere<sup>5</sup>. Figure 1 shows the amino acid sequences of the various encoded fusion proteins of plac1947, p241.1947 and p241.CB15 and rat preproinsulin, for comparison. Equal

amounts of late log cells were labelled with 35SO42- and either lysed with lysozyme and Triton X-100 to produce a whole cell lysate or digested with lysozyme in sucrose to release the contents of the periplasmic space. Immunoprecipitated insulin antigen was electrophoresed on a 7-15% gradient Laemmli<sup>10</sup> SDS-polyacrylamide gel. Figure 2 shows an autoradiograph of the gel; the three whole-cell samples are on the left, the three periplasmic samples are on the right. Only 9% of the insulin antigen of the non-secreting control, p241.CB15 (whole cell lysate, lane 1; periplasmic contents, lane 6), is released during lysozyme-EDTA digestion, as determined by densitometer tracings; thus, less than 10% of the cells lyse during the treatment to release the contents of the periplasm. Both the new construction, plac 1947 (whole cell lysate, lane 2; periplasmic content, lane 5), and the control, p241.1947 (whole cell lysate, lane 3; periplasmic content, lane 4), efficiently secrete insulin antigen into the periplasm. Moreover, the  $\beta$ -galactosidasepreproinsulin fusion protein seems to be correctly processed to proinsulin, as it co-migrates in a tight band with the immunoprecipitated protein product of p241.1947, which has been sequenced to prove that it is correctly cleaved to proinsulin6. The protein product of p241.CB15, which is not secreted, is 22 amino acids longer<sup>5</sup> than proinsulin and migrates above the proinsulin band. These data are consistent with the hypothesis that the protein product of the  $\beta$ -galactosidase-preproinsulin gene construction is also properly processed to proinsulin, although a difference of one or two amino acids cannot be ruled out.

٠.;

Our data show that a cukaryotic signal sequence, preceded by 18 amino acids at its amino terminus arising from DNA sequences totally unrelated to any signal peptide, can still direct efficient secretion and also probably correct clipping. Lingappa et al. have proposed that ovalbumin contains an internal signal sequence; our experiment supports the concept that the hydrophobic core need not be immediately at the amino terminus to function, although there are limits to the functional placement of the signal sequence. Bedoulle et al. 12 have used genetic techniques to fuse most of the gene for a bacterial periplasmic protein, the maltose binding protein, to most of the gene for  $\beta$ -galactosidase.  $\beta$ -Galactosidase enzymatic activity was not detected in the periplasm, but was present in the inner membrane and cytoplasmic fractions<sup>12</sup>. Thus, the instructions for secretion can be overruled if other regions of the protein obscure the presence of a signal sequence or, once secretion is initiated, inhibit completion of secretion.

Fig. 1 Comparison of the DNA sequence across the fusion region in placi 1947 and amino acid sequence of the encoded hybrid  $\beta$ -galactosidate-preproissulin protein product with the amino acid sequences of the three hybrid prepenicillinase-prepromisilin protein products<sup>3</sup>. The DNA sequence begins at the fMet codon of  $\beta$ -galactosidase, contributed by pExlac 150, and ends at the seventh codon of the pre-proinsulin signal sequence, contributed

by a HindIII-terminated cDNA meert encoding rat prepromsulin, with the intervening codons (underlined) contributed by an EcoRI-HindIII linker and the poly-GC tails of the preproinsulin insert. Each line of amino acid sequence represents one continuous sequence which has been grouped from left to right to emphasize similarities and differences as follows: first group, β-galactosidase amino acids; second group, preproinsulin as amino acids; third group, amino acids encoded by DNA linkers and the poly-GC tails of certain preproinsulin gene inserts; fourth group, preproinsulin as an acids; fifth group, proinsulin amino acids; through the fourth amino acid. The protein product of p241.1947 is effectively secreted by bacteria, where the protein product of p241.E15 is not secreted at all? A = Aia, C = Cys, D = Asp, E = Glu, F = Phe, G = Gly, H = His, I = Ile, K = Lys, L = Leu, M = Met, P = Pro, Q = Gln, R = Arg, S = Ser, T = Thr, V = Val, W = Trp plac1947 was constructed as follows: 0.2 μg of the Print-terminated cDNA insert from p241.1947, encoding the gene for preproinsulin (but minus the first three codons) and solated by the methods described elsewhere<sup>13</sup>, was incubated with 1.4 units of E. coli DNA polymerase I (Klenow fragment, New England Biolabs) for 2 h at 37 °C in 50 μ N 10 mM Tris-HCl pH 7.5, 10 mM MgCl<sub>22</sub>. 1 mM dithicthretiol (DTT), 50 mM NaCl, 0.1 mM dCTP. The mixture was phenol extracted, ethanol precipitated and spun in a deak-top clinical centrifuge for 2 min through 2 ml Sephadex G-50 (Pharmacia) in 20 mM NaCl. The ethanol precipitation was resuspended in 10 μ 150 mM Tris-HCl pH 7.6, 10 mM MgCl<sub>22</sub>, 1 mM DTT, 1 mM ATP, and incubated with 0.2 μg of kinased HindIII linker (Collaborative Research) and 15 units of T4 DNA lagase (New England Biolabs) overnight at 15 °C. After phenol extraction and ethanol precipitation, the fragment was subcloned into HindIII (New England Biolabs) for 4 h at 37 °C in 100 μl 10 mM Tris pH 7.6, 10 mM MgCl<sub>23</sub> 1 mM DTT and 50 mM NaCl. The cut fragment was subcloned into Hi

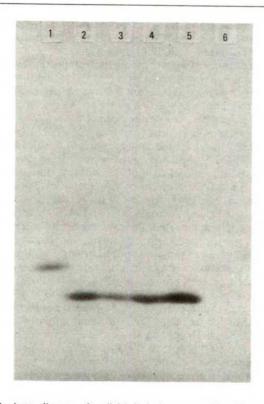

Fig. 2 Autoradiogram of radiolabelled, immunoprecipitated protein products of three preproinsulin constructions in E. coli K-12 strain PR13 fractionated for whole cell contents or for the contents of the periplasm. Lane 1, p241.CB15, whole cell; lane 2, plac1947, whole cell; lane 3, p241.1947, whole cell; lane 4, p241.1947, periplasm; lane 5, plac1947, periplasm; lane 6, p241.CB15, periplasm. Cells bearing the preproinsulin plasmids were grown in  $2YT^{17}$  overnight.  $100 \,\mu$ l were inoculated into  $10 \,\mathrm{ml} \,\mathrm{S}$  medium<sup>18</sup> supplemented with  $10 \,\mu\mathrm{g} \,\mathrm{ml}^{-1}$  thiamine,  $40 \,\mu\mathrm{g} \,\mathrm{ml}^{-1}$  L-threonine, and  $40 \,\mu\mathrm{g} \,\mathrm{ml}^{-1}$  L-leucine, and grown to an  $A_{550}$  of 0.7–0.85 at  $37 \,^{\circ}\mathrm{C}$ .  $5 \,\mathrm{mCi} \,\mathrm{H}_2^{35}\mathrm{SO}_4$  (carrier-free, NEN) were added to the cells, which were allowed to grown for a further  $10 \,\mathrm{min}$  then collected and superproduction. were allowed to grow for a further 10 min, then collected and resuspended in  $400 \mu l$  50 mM Tris-HCl pH 8, 25% sucrose. The cells were divided into two 200- $\mu l$  aliquots which were both incubated on ice for 15 min with 50  $\mu l$ lysozyme in 20 mM EDTA pH 8. A whole-cell fraction was prepared from one of the 200-µl aliquots by lysing the cells with 750 µl 150 mM Tris-HCl pH8, 0.2 M EDTA, 2% Triton X-100, and pelleting the cell debris by centrifugation for 1 h at 16,500 r.p.m. in a Sorvall SA-600 rotor. A periplasmic fraction was prepared from the other 200-µl aliquot by centrifugation for 20 min at 8,000 r.p.m. in a Sorvall SS-35 rotor and dilution of the supernatant with 750  $\mu$ l of the Triton buffer described above. Both fractions were incubated for 1 h at 37 °C with an amount of anti-insulin serum (an IgG fraction), that is in a 1,000-fold excess over the insulin antigen level in p241.1947 (determined by radioimmunoassay5). 100 µl of heat killed, formalin-treated Staphylococcus aureus (10% v/v, prepared by the method of Kessler<sup>19</sup>) was added, incubated on ice for 30 min and washed by the method of Kessler<sup>19</sup>. The *S. aureus*-radiolabelled antigen complexes were prepared as previously described<sup>6</sup>, except that the samples were resuspended in  $50 \,\mu l$  sample buffer and electrophoresed on a 7-15% polyacrylamide gradient gel using Laemmli buffers10 supplemented with 2 mM EDTA. The cells harbouring plac 1947, p241.1947 or p241.CB15 were grown to  $A_{550}$  0.84, 0.76 and 0.74, respectively. Equal whole-cell and periplasmic samples were loaded as follows: plac 1947, 1 µl; p241.1947, 1 µl; p241.CB15, 2.5 µl. The gel was destained, dried and autoradiographed for 6.h on Kodak X-omat AR-5 film. The film was scanned with an Ortec 4310 densitometer. The actual gel was 20 cm, but only a 3-cm portion is shown here; no other bands appeared in the lanes. By standard liquid radioimmunoassay, described elsewhere<sup>5</sup>, plac 1947 makes ~1,500 molecules per cell in PR13 (I. Akerblom, personal communication), a whole-cell insulin antigen level similar to that of p241.19475. All manipulations involving cells bearing preproinsulin plasmids were done under P1 containment according to NIH guidelines.

We thank Heinz Schaller for the gift of plasmids, Ingrid Akerblom for the gift of antiserum and a radioimmunoassay, Jesse Hochstadt for one DNA sequencing run, and Jim Kaufman for the gift of heat-killed formalin-fixed Staphylococcus aureus and for running the gel in Fig. 2. Laboratoire de Génétique Moléculaire des Eucaryotes du CNRS, Unité 84 de Biologie Moléculaire et de Génie Génétique de L'INSERM, Institut de Chimie Biologique, Strasbourg, France

In most, but not all, eukaryotic genes transcribed by polymerase B (II)1-5, the site of initiation of transcription is preceded by a TATATAT sequence4, commonly referred to as the Goldberg-Hogness<sup>6</sup> or TATA box, which seems to be required for the generation of faithful 5' termini of mRNAs<sup>7-14</sup>. For all genes except one<sup>9,12,15-17</sup>, deletion of the TATA box reduces the rate of mRNA synthesis<sup>7,10,11,13,18-23</sup>. Point mutations in the TATA box of the chick conalbumin gene diminish transcription in vitro 20-40-fold<sup>21,24</sup>. The question remained of whether this effect would persist in vivo where far upstream sequences dramatically modulate gene expression 7-11,25,26. Unfortunately the chicken conalbumin gene is poorly expressed when introduced into eukaryotic cells in culture (B.W., unpublished results) or into Xenopus oocytes (S. Swany, personal communication). We have therefore constructed a new gene unit with a chimaeric promoter region by introducing the conalbumin wild-type or mutated TATA box region into the sea urchin H2A histone gene, which is known to be efficiently expressed in Xenopus oocytes<sup>27-29</sup>. We report here that with both the wild-type and mutated chimaeric promoters, initiation of transcription occurs at a novel initiation site about 26 nucleotides downstream from the TATA or TAGA boxes, but in the mutant case, the amount of specific transcripts is decreased fivefold.

The scheme for construction of the chimaeric promoter was based on restriction maps and sequencing data of the conalbumin<sup>30</sup> and the H2A histone genes<sup>7,31</sup> (see Fig. 1 legend). This enabled us to assemble a novel gene with a chimaeric promoter which we called H2Ac. The TATA- and the TAGA-H2Ac genes were subsequently reintroduced into the 6-kilobase (kb) histone DNA repeat unit, in the place of the wild-type H2A gene. Successful construction of the chimaeras was confirmed at this stage by DNA sequencing<sup>32</sup>. Our sequence manipulations leave the upstream modulator sequences8 and the initiator

Fig. 1 Structure of the 5'-flanking region of the H2A wild-type and mutant genes in the context of the 6-kb histone gene repeat unit. The structural maps of the exchanged DNA segments are shown in the context of the wild-type sequences remaining. A-D Depict the nucleotide sequence of the TATA/TAGA region of the chicken conalbumin, the chimaeric TATA/TAGA H2Ac, the wild-type H2A and the TATA box deletion H2A genes respectively. The exchanged DNA segments are indicated by boxes. The chimaeric promoter mutants contain two extra nucleotides originating from a BamHI linker (A). Conserved sequences underlined. ●, Map positions of the various H2A mRNA 5' ends (see Fig. 3); ○, the conalbumin mRNA 5' end<sup>30</sup>. The numbering of the TATA-H2Ac gene refers to the initiation codon of the gene as +1. The chimaeric H2A histone/conalbumin gene promoter mutants were constructed as follows. To replace the TATA box region of the H2A histone gene with the equivalent fragment of the chicken conalbumin gene, we first constructed pBR322-TATA and -TAGA recombinants. Short fragments containing these sequences were prepared from the appropriate mutant and wild-type conalbumin DNAs<sup>21,24</sup> by digestion with BstNI (-44) and MboII (-9). The ends of each fragment were flush-ended with T4 DNA polymerase. After heat inactivation, <sup>32</sup>P-labelled BamHI

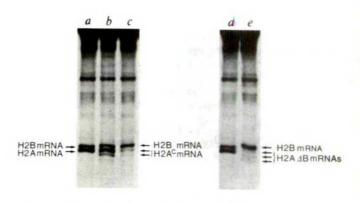

linkers were ligated to the flush ends. After BamHI restriction, the DNA fragments terminating in Bam sequences were purified and cloned into the BamHI site of pBR322. After amplification, the cloned TATA- and TAGA-containing BamHI fragments were recovered and treated with HaeIII enzyme to remove the Bam-linker sequence at the 3' end of the coding strand. The resulting fragments were ligated to the HincII-Xho fragment of the H2A gene<sup>7</sup> and the appropriate product selected by gel electrophoresis. The selected DNA fragments were ligated to the 90-bp EcoRI-Sau3A fragment of the pBR H2A-3 DNA<sup>7</sup> and inserted into an EcoRI-XhoI-cleaved pBR H2A-3 vector lacking the EcoRI-XhoI fragment. The TaqI-XhoI fragments of the resulting recombinants were inserted into the h22 DNA recombinants as described elsewhere<sup>7</sup>.

segment<sup>7</sup> untouched. The distance of the modulator from the TATA box differs in the H2A and the chimaeric H2A<sup>c</sup> gene by only 5 nucleotides and between TATA box and initiator segment by 10 nucleotides, as the exchanged TATA box segments were of nearly identical size (see Fig. 1). The circularized repeat unit, free of vector DNA, was injected into *Xenopus* oocyte nuclei together with  $[\alpha^{-32}P]GTP^{33}$ . Total labelled RNA was isolated and analysed by gel electrophoresis and autoradiography. Expression of the wild-type and mutant H2A genes was monitored in each case against the transcription of the H2B gene which, residing within the same DNA molecule, served as an internal control.

Figure 2b shows that the chimaeric TATA-H2Ac gene produces a novel H2A° mRNA which is resolved into two bands on the electropherogram; the more slowly migrating of these is almost certainly a conformational artefact in this partially denaturing gel system<sup>34</sup> because trimming of the mRNA-DNA hybrids with mung bean nuclease by the modified Berk and Sharp procedure<sup>35,36</sup> produced a single protected DNA band (see Fig. 3b). The TATA-H2Ac gene is transcribed as rapidly as the wild-type H2A gene (Fig. 2a, b). Calculation of the H2A mRNA synthesis by densitometric tracing of the autoradiogram was performed as described elsewhere7. The 5' terminus of the H2Ac mRNA was mapped with mung bean nuclease36 to nucleotide position -66 of the TATA-H2Ac gene (Fig. 3b, e-h) 26 nucleotides downstream of the TATA box (see Fig. 1). In both the wild-type conalbumin and H2A genes, the distance of the initiation site from the TATA box is 28 nucleotides (see Figs 1 and 3, a and b). A hierarchical relationship between the TATA box and the initiator segment<sup>7,8</sup> is again apparent in that the former determines the distance to the initiation site which, however, can be modified by a few nucleotides if a favourable base composition<sup>8</sup> such as CAA or CAT (see Fig. 1) in the sequence ladder is available. The TAGA-H2Ac gene produces what seems to be an identical transcript to the TATA-H2A' mRNA, but at a reduced rate, calculated to be one-fifth of the transcription rate of the TATA-H2A° gene (Fig. 2c). A similar reduction in transcription rate is found for the TATA box deletion mutant (Fig. 2e and ref. 7). The 5' terminus of the TAGA-H2A° transcript has been mapped to the same nucleotide position (Fig. 3d) as the TATA-H2A° mRNA 5' end. This contrasts with the transcripts detected after injection of the TATA box deletion H2A mutant7 which exhibit a pronounced heterogeneity of 5' ends, as seen in Fig. 3c.

Note that the chicken DNA fragment, although differing in sequence from the substituted sea urchin segment except for the TATA box, can nevertheless replace it functionally. In addition, the natural initiation site, although left untouched, is not used for initiation of transcription of the H2A° gene unit, presumably because it is too close to the replaced TATA box. These observations are further evidence for the importance of the TATA box sequence per se, and for its predominance in selecting the first nucleotide(s) of the initial transcripts<sup>7,9,12–14,17</sup>.

This work shows the importance of the TATA box for transcription in vivo, and particularly of the second T in the sequence. A single base change, from T to G, in the third position of the TATA sequence, does not alter the site of RNA chain initiation, but reduces the rate of transcription by a factor of five. A deletion of the TATA box in the H2A gene also decreased transcription fivefold. The in vivo effects of the TAGA box mutation are consistent with the in vitro results, where the T to G mutation decreased the rate of transcription

**Fig. 2** Gel analysis of total RNA from microinjected oocytes. Wild-type and mutant 6-kb DNA circles (4 ng per oocyte) were injected together with 0.3 μCi of  $[\alpha^{-32}P]GTP^{33}$ . The RNA was extracted and analysed as described elsewhere <sup>7,34</sup>. The labelled endogenous *Xenopus* RNAs are visible in the upper sections of the gel slots. a-c, RNA of oocytes injected with h22 wt, TATA-H2A $^c$ , TAGA-H2A $^c$  DNA; d-e, RNA from h22 wt and h22 ΔB (TATA box deletion) <sup>7</sup> DNA. The positions of the histone mRNAs are indicated. The amounts of RNA loaded onto each slot correspond to a sample of two oocytes.

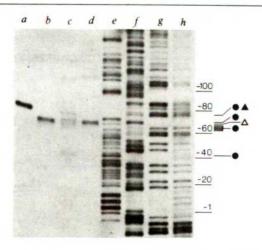

Fig. 3 Mung bean nuclease mapping of the 5' ends of H2A mRNA. For the mapping experiment, total unlabelled RNA from oocytes injected with wild-type and mutant DNAs were purified on CsCl step gradients, hybridized to their cognate 0.9-kb *Hinf-Xho*I DNA fragments<sup>31</sup>, 5'-<sup>32</sup>P-labelled at their *Xho*I site (see Fig. 1) and treated with mung bean nuclease as described elsewhere a-d, Labelled DNA fragments protected by RNA from h22 wildtype, TATA-H2A<sup>c</sup>, h22  $\Delta B$  (TATA box deletion) and TAGA-H2A<sup>c</sup> templates, respectively. The amount of protected DNA fragments in a and b correspond to RNA from 0.3 oocytes; for c and d the amount of DNA fragments loaded onto the slots was increased fivefold to facilitate comparison with a and b. e-h Are the G,A,C,T DNA sequencing reactions<sup>32</sup> of the *Hind-XhoI* DNA fragment of TATA-H2A<sup>c</sup> DNA. The numbering of the nucleotide sequence is that of Fig. 1b. Symbols at the side denote the uncorrected H2A mRNA 5' map positions: ▲, h22 wild-type; △, TATA and TAGA-H2A<sup>c</sup>; and ●, h22 ΔB (TATA box deletion) mRNAs.

20-fold and did not change the site of RNA chain initiation<sup>21,24</sup>. The less drastic reduction of transcription observed with the TAGA box mutant, relative to the in vitro studies, may be due to the activity of the modulator sequences in the in vivo system. Almost all the 5' termini of the TAGA-H2A' transcripts can be mapped to a single (or at least predominant) initiation site with few, if any, transcripts initiating further upstream, while transcripts of TATA-deletion mutants in H2A and other genes quite frequently show a plurality of 5' termini7.9-12. If, as speculated, the TATA box serves to guide the RNA polymerase into a correct initiation frame<sup>7,13</sup>, a T to G mutation may simply promote a less productive 'initiation complex'. Because such a complex may still represent, energetically, the most favoured structure, alternative starting points, readily detected in TATAdeletion mutants, cannot arise.

Some eukaryotic genes known to be expressed at high rate, such as viral 1.4,37 genes and the predominant H4 gene of two sea genes and the predominant H4 gene of two sea urchins5, do not have recognizable or very deformed TATA boxes. It will be of interest to learn what controls initiation of transcription in these cases.

We thank Dr M. Chipchase for critical reading of the manuscript and Mrs S. Oberholzer and Mr F. Ochsenbein for assistance in preparing the manuscript. This work was supported by Swiss NRC grant 3.743.80 and the Kanton of Zürich.

‡ Radiobiology Department, Yale University Medical School, 333 Cedar Street, New Haven, Connecticut 06510, USA

Radiation-induced mutagenesis of Escherichia coli depends on the ability of the bacteria to perform error-prone repair 1,2. This SOS repair activity is induced by irradiation of bacteria and gives rise to mutations both at the site of radiation-induced lesions (targeted mutations) and in undamaged DNA (untargeted mutations)1,3-6. To elucidate the relative contributions of targeted and untargeted mutations to  $\gamma$  and UV radiation mutagenesis we have determined the DNA sequences of 174 M13 revertant phages isolated from stocks of irradiated or unirradiated amber mutants grown in irradiated (SOS-induced) or unirradiated (non-induced) host bacteria. As reported here, differences in the spectra of base change mutations induced in the various conditions were apparent, but we detected no obvious specificity of mutagenesis. In particular, in our conditions, pyrimidine dimers did not seem to be the principal sites of UV-induced base substitution mutagenesis, suggesting that such mutagenesis occurs at the sites of lesions other than pyrimidine dimers, or is untargeted.

We used single-stranded DNA phage M13 to study independently the effects of target DNA irradiation and the consequences of induction of the SOS repair system. M13 is particularly useful in such an investigation because (1) mutagenesis of single-stranded DNA phages by UV and  $\gamma$

iog phase cultures of KA798 and KA805 SupD grown with bubbling at 32 °C to an  $A_{560}=0.3$  were divided into two portions, one of which was irradiated with UV light. The cultures were grown in the dark for a further 20 min to maximize SOS induction<sup>4</sup> and were then infected with intact or irradiated M13 phage. After adsorption at room temperature for 3 min the infected bacteria were plated out and incubated overnight at 37 °C. Plaques were counted and revertants picked for DNA sequence analysis. In experiments with am6H1 phage, the UV dose to phage was 90 J m<sup>-2</sup> and to the host bacteria 50 J m<sup>-2</sup>. In experiments with am7H3 phage, phage were irradiated with 60 J m<sup>-2</sup> and the host bacteria with 60 J m<sup>-2</sup>. The  $\gamma$ -ray dose (in broth in air) was 1.5 Mrad. Mutation frequencies are the proportion of revertant phages (titred on KA798) to total phages (titred on KA805 SupD); standard deviations are given in parentheses.

irradiation is dependent on the activity of the same  $recA^+$  and  $lexA^+$  bacterial genes that are required for the induction of all SOS functions in  $E.\ coli$ , including radiation mutagenesis<sup>5.6</sup>, (2) its single-stranded DNA is not subject to error-free repair by excision<sup>7</sup> or by multiplicity reactivation (recombination repair)<sup>8</sup>, and (3) its DNA has been completely sequenced<sup>9</sup> and, as it is single stranded, it is possible unambiguously to identify the exact bases involved in any sequency alteration.

Forty-nine revertants of am6H1 and 125 revertants of am7H3 were isolated from populations of irradiated and unirradiated phages grown in irradiated and unirradiated bacteria (Table 1), and the DNA sequence in the region of the amber codon was determined by the Sanger method<sup>9,10</sup>. Figure 1 shows the number of occurrences of each reversion sequence. Except for the  $TAG \rightarrow GAG$  transversion, which was not found for either amber, all other detectable single-nucleotide changes were observed. ( $TAG \rightarrow TAA$  produces an ochre nonsense codon which would not have been detected as a revertant.) Our failure to detect any GAG revertants might have been due to the infrequency of the  $T \rightarrow G$  transversion or the inability of glutamic acid to substitute for glutamine at these two sites.

The limited number of mutants that can be analysed by DNA sequencing imposes a limit on the significance of differences observed between the spectra of base changes induced by various treatments. An additional problem is that pre-existing mutants may make a significant contribution to the spectra for spontaneous revertants and revertants isolated after those treatments which result in reversion frequencies close to the spontaneous frequency. (Reconstruction experiments showed no significant growth advantage or disadvantage of revertants.) In an attempt to minimize the problems of pre-existing revertants, several stocks of the amber phages were prepared from isolated plaques for each experiment. For those treatments resulting in an elevated reversion frequency, the fact that the revertants were isolated from infective centres ensures that they arose independently, and are therefore more likely to represent accurately the mutational spectrum.

In addition to increasing the frequency of mutations of unirradiated phage, UV irradiation of host cells increased the variety of base changes. Some of the base changes found among these untargeted mutants had not been detected in the spontaneous spectra, while some of the base changes found frequently in the spontaneous spectra were less common in the untargeted spectra. This finding agrees with reports that in addition to increasing the frequency of mutation of unirradiated and irradiated phage, induction of the SOS repair system may alter the specificity of mutagenesis<sup>6,11</sup>. No increase in the mutation frequency was observed when UV-irradiated phage were grown in unirradiated hosts, but a considerable increase was observed when they were grown in UV-irradiated hosts (Table 1)3,4,6. This implies that UV photoproducts in target M13 DNA are not directly mutagenic, but that they are mutagenic when the SOS repair system has been induced. To assess the role of pyrimidine dimers in this mutagenesis we had chosen to study two amber mutants in which the thymine had the potential to be dimerized with a neighbouring thymine in the preceding codon. (Furthermore, in the case of the am6H1 mutant the third base of the preceding valine codon could be replaced by any other nucleotide without changing the sense of this codon.) Few of the UV-induced mutants of am6H1 involved the thymine. On the other hand, the T+C transition seemed to make a major contribution to targeted mutagenesis of am7H3, but this transition also contributed significantly to untargeted mutagenesis of this mutant. The fact that UV-induced mutations frequently involved the adenine and guanine bases of both amber mutants suggests that pyrimidine dimers are not the main sites of base substitution mutagenesis in UV-irradiated M13 DNA. Two alternative possibilities are that photoproducts other than pyrimidine dimers are important targets for UV-induced base substitution mutagenesis or that pyrimidine dimers can have distal mutagenic effects on the same molecule.

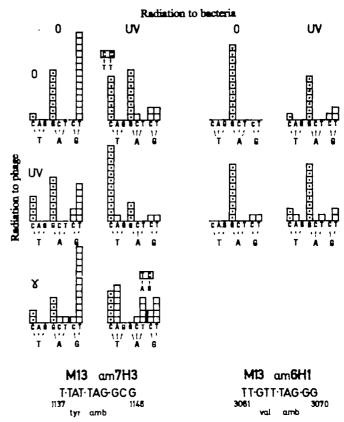

Fig. 1 DNA sequences of revertants of irradiated and unirradiated M13 am7H3 and am6H1 grown in UV-irradiated and unirradiated bacteria. Revertants from the experiments shown in Table 1 were isolated and their DNA sequences in the region of the amber mutation determined by the Sanger method<sup>9,10</sup>. For am6H1 the M13 Hhal fragment 5 (ref. 19) was used as primer, and for am7H3 the M13 Thal fragment 1 (ref. 19) was used After extension by E. coli DNA polymerase I, Klenow subfragment, the primers were removed by Hhal digestion and the products analysed on 12% polyacrylamide gels. Each box corresponds to an independently isolated revertant: D, transition; LXI, transversion; XXI, tandem base changes.

 $\gamma$ -Induced mutagenesis of E. coli depends on the recA<sup>+</sup> and lexA+ gene functions, but seems less dependent on SOSinduced de novo protein synthesis<sup>2</sup>. Consistent with this finding,  $\gamma$  irradiation of am7H3 was mutagenic even when the phage was grown in unirradiated hosts. However, growth of  $\gamma$ -irradiated phage in UV-irradiated hosts increased mutant vields considerably, suggesting that  $\gamma$  irradiation, like UV irradiation, also causes DNA damage whose mutagenic potential is only realized in SOS-induced cells<sup>12</sup>. Insofar as the spectra of base changes induced by y and UV irradiation differ (difficult to assess on the small sample shown here, but see refs 11, 13, 14), these lesions are likely to be different, a predictable conclusion in view of the different DNA lesions caused by UV and y irradiation15

Other investigators (ref. 13 and refs therein) have found that UV light sometimes induces tandem base change mutants whose appearance has been considered as evidence of mutations occurring at the sites of pyrimidine dimers 1.5,13. In our experiments two such mutants were found in phage grown in UVirradiated hosts, but neither of these could be attributed to targeted mutations at the sites of pyrimidine dimers, as one was from unirradiated phage and the other involved two purines. These mutants, and the fact that both UV and  $\gamma$  irradiation induced a wide variety of different base changes in M13 (Fig. 1) and in the lac i gene of E. coli<sup>13,14</sup>, raise the possibility that induction of the SOS repair system, by UV or  $\gamma$  radiation, causes clusters of targeted and untargeted base changes. The observation that non-tandem double base changes in the anticodon sequences of an E. coli tRNA gene occur at much higher frequencies after UV irradiation than expected from the frequency of single base mutants<sup>16</sup> supports this idea.

The contribution of untargeted mutagenesis mutagenesis may be higher for phage genomes than for bacterial genomes, because phage DNA experiences more rounds of replication in the presence of SOS mutator activity<sup>1</sup> and because post-replicative mismatch correction<sup>17</sup> of untargeted mutations may be less efficient for phage DNA. Our data indicate that, in the conditions used, thymine dimers are not the principal sites of UV-induced base substitution mutagenesis of phage M13. If this is a general phenomenon, the photoreversibility of the mutagenic effects of UV on bacteria 18 and the photoreversibility of the UV induction of the SOS repair system<sup>3</sup> may indicate that pyrimidine dimers are primarily inducing lesions for a process (SOS repair) necessary for targeted and leading to untargeted mutagenesis.

# Preferential cleavage of phage $\lambda$ repressor monomers by recA protease

Sara Cohen\*, Brian J. Knoll†, John W. Little & David W. Mount‡

Department of Molecular and Medical Microbiology, College of Medicine, University of Arizona, Tucson, Arizona 85724, USA

Expression of phage lytic functions in  $\lambda$  lysogens of Escherichia coli is prevented by phage repressor, which binds to specific operator sequences on the prophage DNA. Phage induction accompanies the expression of an entire set of 'SOS functions', which occur when host DNA is damaged or DNA synthesis is interrupted. In these conditions,  $\lambda$  repressor is thought to be inactivated by recA protease, thereby leading to expression of phage lytic functions1. We have now characterized the repressor from a  $\lambda$  mutant, ind'-1, which, as prophage, is more easily induced than wild-type phage by a weak inducing treatment2. At high concentrations,  $\lambda ind^3$ -1 repressor differs from wild-type repressor in two ways: whereas wild-type repressor forms dimers and becomes relatively resistant to the recA protease, a much greater proportion of \(\lambda ind^s-1\) repressor remains monomeric and the protein remains sensitive to the protease. These findings support previous indications<sup>3</sup> that repressor monomers are the preferred substrate for protease, both in vivo and in vitro.

Phage  $\lambda$  repressor has two functional and physical domains: an amino-terminal one determining operator recognition and a carboxy-terminal one determining the formation of repressor oligomers<sup>4</sup>. As only dimers of repressor bind to phage operators with high affinity and specificity<sup>4,5</sup>, separation of the two domains by proteolytic cleavage should inactivate the protein, and indeed, the purified N-terminal fragment binds to opertor DNA with 10<sup>4</sup>-fold lower affinity than does intact repressor<sup>4</sup>. In vivo and in vitro the recA protease specifically cleaves repressor into the two domains, thereby inactivating it<sup>1,1</sup>

Two lines of evidence suggest that  $\lambda$  repressor dimers are relatively resistant to the recA protease. In vitro, the fraction of repressor cleaved, as measured by inactivation of repressor DNA binding activity, decreases at repressor concentrations where a significant proportion of repressor exists as dimers<sup>3</sup>. This effect is not due to saturation of the protease, because the rate of cleavage of admixed P22 repressor is unaffected even by high levels of  $\lambda$  repressor<sup>3</sup>. In vivo, induction of  $\lambda$  is deficient in a cell which overproduces repressor, whereas the heteroimmune phage  $\lambda$  imm<sup>434</sup>, present as a prophage, is normally inducible in such cells7

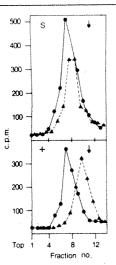

To test further whether repressor dimers are protease resistant, we have characterized the repressor of the hyperinducible mutant,  $\lambda ind^{s}-1$ . Because this mutation lies in the region of cI, which encodes the C-terminus of repressor (see Fig. 1), we thought that \(\lambda ind^s-1\) repressor might be altered in its ability to dimerize and might therefore have increased susceptibility to recA protease at high concentrations.

Two in vivo tests argue against the possibility that  $\lambda ind^{s}-1$ induces more readily because its repressor is defective in operator binding: (1) the mutant can form lysogens as efficiently as λind<sup>+</sup> phage<sup>8</sup>; and (2) while the rate of spontaneous phage release from a  $\lambda ind^{s}-1$  lysogen of a  $recA^{+}$  host is an order of magnitude higher than for  $\lambda ind^+$ , there is no spontaneous phage production by the mutant prophage in a recA host, which lacks recA protease activity (unpublished observations). We conclude that the \(\lambda ind^{\sigma} - 1\) repressor is functionally stable in vivo and likely to be altered in its interaction with the protease.

1 Sedimentation of \(\lambda ind^\*-1\) S-labelled and \(\lambda\)ind\* repressors. repressor was diluted to  $4 \times 10^{-9}$  M in a buffer containing 0.01 M PIPES pH 6.9, 0.2 M NaCl, 1 mM EDTA, 0.1 mM dithiothreitol, 50 µg ml Jovine serum 10 mg ml<sup>-1</sup> albumin bovine haemoglobin marker (1), either with (A) or without ( unlabelled repressor at 10" Following 90 min incubation at 0 °C to establish the monomer-dimer equilibrium, 0.3 ml of each sample was layered on a 5-ml 5-20% sucrose gradient in the same Gradients were centrifuged in a Beckman SW60Ti rotor for 20 h at 59,000 r.p.m. at 4 °C, 0.3-ml fractions were collected, the position of the haemoglobin marker determined, haemoglobin added to each fraction up to this same peak level to standardize the counting buffer and the radioactivity of each fraction

measured. Bottom panel, ind\*; top panel, ind\*-1. To determine the position of ind\*-1 on the A genetic map, Aind\*-1 sus 029 was crossed with various A  $spi^-$  mutants with deletions which end in cI or left of cI (ref. 11). Because  $spi^-$  phage fail to grow on a  $recA^-$  host,  $sus^+$   $spi^+$  phage produced by recombination between the right end of the spi deletion and sus 0+ could be selected by plaque formation on recA sup bacteria. At least 1,000 of these recombinants were scored for the presence of ind\*-1 by their plaque type on DM1285, on which ind\* and ind\*-1 phage form turbid and clear plaques respectively<sup>12</sup>. These crosses established that ind\*-1 lies between the right ends of spi-23 and spi-91 (ref. 11), placing it in the left one-third of cI or in the right end of rex. This map location was verified by in vitro recombination. To facilitate purification of ind\*-1 repressor, plasmid pKB280 (ref. 13) was modified to overproduce ind\*-1 mutant repressor. A 520-base pair HindIII fragment, which includes the left one-third of the cl gene, was removed from pKB280 to make pBK1; the homologous fragment excised from phage Aind\*-1 was then inserted into pBK1 to produce pBK2. pBK1, which had the portion of cI coding for the NH<sub>2</sub>-terminus of repressor, was resistant to λcI mutants (see also ref. 5). However, pBK1 was sensitive to Avir. Therefore, cells carrying pBK2 could be selected on the basis of their resistance to Avir. The presence of ind\*-1 on pBK2 was confirmed by rescue of ind\*-1 from pBK2 by genetic recombination. Repressor levels in cells carrying pBK2 were lowered by introducing into them F'laciQ1 which overproduces lac repressor<sup>14</sup>. Because the phage repressor genes in pKB280 and pBK2 are fuesed to the lacZ promoter-operator region, the lac repressor reduced the phage repressor levels. After further inducing treatment with mitomycin C, it became possible to superinfect cells with  $\lambda c47$ , which has a clear-plaque mutation near ind\*-1, and thereby to rescue the ind\*-1 alleles by phage plasmid recombination. Phage carrying ind<sup>s</sup>-1 were distinguished from  $\lambda c47$ by production of a turbid plaque on normal indicator C600 and a clear plaque on DM1285, as described previously<sup>12</sup>. Repressor was purified from extracts of cells carrying pKB280 or pBK2 by method (1) of Johnson et al.15 and was estimated to be 98% pure by gel electrophoresis. The mobility of the purified  $ind^*$ -1 repressor in polyacrylamide gels was slightly greater than that of  $ind^+$  (see Fig. 2). By the filter binding assay, the DNA binding activity of one of our preparations of ind\*-1 repressor was found to be twofold less than wild-type repressor purified by the same procedure. While this effect may have resulted from a change in dimer association as described in the text, variability in the same range can be found in different preparations of wild-type repressor 10. Repressor concentrations throughout are given in monomers.

Plasmid pBK2, which overproduces  $ind^s$ -1 repressor, was isolated and used as a source of mutant repressor (see Fig. 1) to be compared with wild-type repressor for its ability to form oligomers and to serve as substrate for recA protease. The repressor concentration in these experiments was in the range  $4 \times 10^{-9}$ - $1.4 \times 10^{-6}$  M, which was achieved by adding varying quantities of unlabelled repressor to a small quantity of <sup>35</sup>S-labelled repressor and incubating for a period of time to allow establishment of equilibrium between monomers and higher oligomeric forms of repressor. Results were analysed by monitoring the labelled repressor. Oligomer formation was compared by measuring sedimentation rates in sucrose gradients.

Wild-type repressor sedimented faster at  $10^{-6}$  and  $10^{-7}$  M than at  $4\times10^{-9}$  M, as expected<sup>9</sup>, indicating oligomerization at the higher concentrations (Fig. 1 and data not shown). By contrast, the sedimentation rate of *ind*<sup>5</sup>-1 repressor did not increase significantly except at the highest concentration

 $(10^{-6} \text{ M})$ . Oligomerization of monomeric  $ind^s$ -1, compared with wild-type, repressor therefore appeared to be far less extensive.

The kinetics of repressor cleavage by the recA protease was then determined in a purified system by measuring one of the cleavage products. Aliquots were taken at various times and analysed on SDS-polyacrylamide gels; repressor concentration varied in twofold steps. The rates of cleavage were estimated by densitometric scanning of autoradiograms (Fig. 2) and are summarized in Table 1. In the experiment shown, excess unlabelled ind+ repressor, added to a low concentration of labelled ind+ repressor, partially protected the latter from cleavage by recA protein. Furthermore, as repressor concentration increased, its rate of cleavage progressively decreased from that expected if it were proportional to repressor concentration. Consistent with previous studies measuring inactivation of repressor and as argued previously<sup>3</sup> (see above), this effect was not due to saturation of the protease, because (1) the same pattern was observed at a higher protease concentration (Table 1) and (2) protease monomers were present in at least a sixfold molar excess over repressor monomers.

By contrast,  $ind^*-1$  repressor was cleaved at a rate nearly proportional to repressor concentration, deviating only slightly at the highest concentration tested  $(1.4 \times 10^{-6} \text{ M})$  (compare Fig. 2a and b; Table 1). As both wild-type and mutant repressors were cleaved at about the same rate  $(4 \times 10^{-9} \text{ M})$ ; Table 1) and both are largely monomers at this concentration (refs 9, 10 and Fig. 1), we conclude that monomers of the two repressors have roughly equal sensitivity to protease. We propose that the  $ind^*-1$  repressor is more sensitive at high concentrations because of its reduced ability to form dimers. These findings therefore provide further evidence that repressor monomers are a preferred substrate for recA protease<sup>3</sup>.

The above properties of  $ind^s$ -1 repressor can probably account for the behaviour of the  $\lambda ind^s$ -1 mutant  $in\ vivo$ . At  $10^{-7}$  M, the concentration estimated to be present in lysogenic cells°, a greater relative amount of  $ind^s$ -1 repressor should be present as monomers, susceptible to the recA protease. Consequently, in a weakly induced cell, in which only a small amount of protease should be activated, a relatively high rate of repressor cleavage would be expected, leading to efficient induction. On the other hand, in a lysogen of wild-type  $\lambda$ , more repressor should be in the form of dimers resistant to cleavage, and should, therefore, bind to operators and maintain the repressed state.

We acknowledge the gift of  $\lambda \ prec A (tif-1) \ c \ I857 \ Q73 \ S7 \ from R.$  Yocum and the communication of unpublished observations

<sup>35</sup>S-labelled repressor was diluted with buffer or unlabelled repressor, allowed to reach monomer-dimer equilibrium and then incubated with recA protein as described in Fig. 2 legend. At 2.5-min intervals, samples were removed until the reaction had run to completion. The reaction was stopped by adding samples to stopping buffer as described <sup>17</sup> and the samples subjected to polyacrylamide gel electrophoresis. Films exposed to the gels were scanned by a densitometer (Quick Scan R&D, Helena Laboratories) to determine the rate of appearance of label in the upper repressor fragment (R1). The time at which 50% of the maximal level of cleavage had occurred was determined from a plot of film optical density at of cleavage in pmol per ml per min was calculated by multiplying the average fractional rate of repressor cleavage during this time by initial repressor concentration. Values separated by commas are measurements from independent experiments. In the reactions in which recA concentrations were 300 μg ml<sup>-1</sup>, DNA was 25 μg ml<sup>-1</sup>. Varying the ratio of unlabelled to labelled repressor in the reaction mixtures did not influence the results.

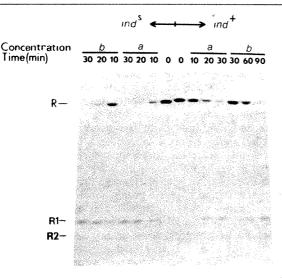

Fig. 2 Influence of repressor concentration on cleavage by recA protein. <sup>35</sup>S-labelled repressor was diluted to  $3.5 \times 10^{-8}$  M in tubes containing 12 mM Tris pH 7.5, 2 mM MgCl<sub>2</sub>, 0.43 mM CaCl<sub>2</sub>, 20 mM NaCl, 43 mM KCl,  $0.54\,\text{mM}$  EDTA,  $1\,\text{mM}$  potassium phosphate pH 7.5,  $2.4\,\text{mM}$  dithiothreitol, 9% glycerol,  $165\,\text{g}\,\text{ml}^{-1}$  bovine serum albumin,  $1\,\text{mM}$   $\gamma$ -thio-ATP and either with (b) or without (a) unlabelled repressor at  $1.4 \times 10^{-6}$  M. ATP and either with (6) or without (2) unlabelled repressor at 1.4 × 10 mer. Following incubation for 90 min at 0 °C to establish monomer-edimer equilibrium, denatured DNA (6  $\mu$ g ml<sup>-1</sup>) was added, the tubes incubated for 5 min at 37 °C, recA (tif mutant) protein added to 70  $\mu$ g ml<sup>-1</sup> and incubation continued at 37 °C. Samples (30  $\mu$ l) were taken at the indicated time and loaded on a 15-25% SDS polyacrylamide gradient gel and electrophoresed. Gels were stained with bromophenol blue, photographed, prepared for fluorography and subjected to autoradiography. R marks the position of the repressor monomer band, R1 and R2 the positions of the carboxyl- and amino-terminal fragments of repressor respectively. ind\*-1 repressor results are shown on the left half of the gel, ind on the right; the centre lanes show uncleaved repressor. Times indicate time of sample removal. Note the later sample times for ind+ repressor cleavage at the high repressor concentration and the increased mobility of  $ind^*$ -1 repressor and its carboxyl-terminal fragment (R1) compared with  $ind^+$  repressor. Repressor bands on stained gels showed intensity changes similar to those on the autoradiogram (not shown). Similar results were also obtained when wild-type recA protein was substituted for the *tif* mutant recA protein. recA protein was purified from extracts of DM1590  $sup^+$  spr-51 lexA3 tif-1 sfiA11 infected with  $\lambda$  precA (tif-1) c1857 Q73 S7 (prepared by R. Yocum and genotype confirmed by us) at a multiplicity of infection of 3. After incubation for 2 h at 37 °C, each litre of cells was collected by centrifugation, suspended in 2 ml 20 mM Tris pH 7.5,  $5 \times 10^{-4}$  M EDTA,  $10^{-3}$  M dithiothreitol, 10% w/v sucrose, 0.2 M NaCl and stored frozen at -20 °C. After thawing, cells were disrupted by sonication and centrifuged for 33 min at 24,000g. recA protein was then purified by polymin P and (NH<sub>4/2</sub> SO<sub>4</sub> precipitation, followed by chromatography on phosphocellulose in potassium phosphate buffer and finally by sedimentation on sucrose gradients as described elsewhere 16. The protein was 99% pure as judged by gel electrophoresis. One A280 unit of recA protein is equivalent to 0.59 mg ml<sup>-1</sup> (J. Roberts, personal communication).

# recA-independent general genetic recombination of plasmids

Richard A. Fishel, Anthony A. James & Richard Kolodner\*

Division of Cancer Genetics, Sidney Farber Cancer Institute and Department of Biological Chemistry, Harvard Medical School, Boston, Massachusetts 02115, USA

The small circular genomes of several bacteriophages and a number of plasmids have been used extensively to study various aspects of the mechanism of genetic recombination. Several studies have demonstrated that the interconversion between the circular monomers and larger circular oligomers of many plasmid DNAs is mediated, at least in part, by the pathway which carries out genetic recombination in wild-type Escherichia coli<sup>1-4</sup>. The recA, recB and recC mutations block conjugationmediated recombination in E. coli<sup>5,6</sup>. However, Clark and his co-workers7.8 isolated two mutations, sbcA and sbcB, which indirectly suppress the recombination deficiency of recB and recC mutations. These indirect suppressor mutations seem to cause recombination by other pathways which require the recA gene product as well as products of other genes such as recF, recJ and recM, which are not normally required for recombination in E. coli<sup>9,16</sup>. Here we report an investigation of the effect of recombination-deficient mutations on plasmid recombination in E. coli. We show that sbcA mutations induce a new plasmid recombination pathway that is 10-15 times more efficient than the normal wild-type recombination pathway and independent of the recA and recF functions.

The E. coli plasmid pVH51 is a 3.8-kilobase (kb) plasmid which codes for immunity to colicin E1 (ref. 11). It forms small numbers of circular oligomers by recombination in wild-type E. coli strains apparently because it lacks a genetic element required for high rates of recombination<sup>4,12</sup>. To study the effect of various recombination-deficient mutations on the recombination of pVH51 DNA, monomeric pVH51 DNA was purified by electrophoresis on preparative agarose gels and used to transform E. coli AB1157 and a number of isogeneic strains containing different recombination-deficient mutations. Plasmid DNA was then purified from the resulting strains and examined for the presence of oligomeric forms by electrophoresis on agarose gels. The results (Fig. 1a) showed that pVH51 DNA formed very few circular oligomers when maintained in E. coli AB1157 (2-4% by weight, determined by electron microscopy) or other wild-type E. coli strains (results not shown). When pVH51 DNA was purified from recA strains (Fig. 1b), recB recC strains (Fig. 1c), recF strains (Fig. 1d) and recB recC recF strains (Fig. 1e) low numbers of circular oligomers were found (<1% by weight). These mutations reduced the numbers of oligomers but their effect is not pronounced as pVH51 DNA forms few oligomers in wild-type E. coli. When strains containing recB recC sbcA mutations (Fig. 1f), recB recC sbcA recF mutations (Fig. 1g) and recB recC sbcA recA mutations (Fig. 1h) were similarly examined, the pVH51 DNA was found to contain high levels of circular oligomers. These results show that the sbcA mutation stimulated the recombination of pVH51 DNA and that the reaction did not require the recA and recF functions.

Studies on the structure of the oligomeric forms of bacteriophage and plasmid DNAs have identified a novel oligomeric form which looks like a figure-8 (refs 13-17) and has many of the properties of a recombination intermediate postulated by Holliday<sup>18</sup> and others<sup>19</sup> to explain both gene conversion and reciprocal exchanges. Similar DNA molecules have been

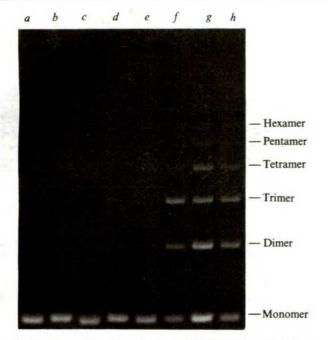

Fig. 1 Electrophoretic analysis of pVH51 DNA purified from isogeneic *E. coli* strains containing recombination-deficient mutations. Monomeric pVH51 DNA was purified from *E. coli* RK1058 recA1 (pVH51) as described elsewhere <sup>37</sup> and the monomeric DNA was further purified by electrophoresis on preparative agarose slab gels<sup>38</sup>. The DNA was then used to transform the *E. coli* strain of interest to resistance to colicin E1<sup>39</sup>. Twelve 10-ml cultures of L-broth were inoculated with a single transformant, grown to a density of 4×10<sup>8</sup> cells ml<sup>-1</sup> at 37 °C and chloramphenicol was added to 250 μg ml<sup>-1</sup>. After shaking for 16 h, plasmid DNA was purified from the cultures and analysed by electrophoresis on a 0.5% agarose slab gel<sup>40</sup>. One representative DNA sample from each strain was further purified by centrifugation to equilibrium in CsCl-Et density gradients<sup>37</sup> and analysed by electrophoresis on a 0.5% agarose slab gel. The DNA samples shown were purified from: a, AB1157 wild type; b, JC2924 recA56; c, JC5519 recB21 recC22; d, JC9239 recF143; e, JC3881 recB21 recC22 recF143; f, JC8679 recB21 recC22 sbcA23; g, JC9610 recB21 recC22 sbcA23.

observed in many systems used to study genetic recombination 20-23. A recombination model for circular genomes which integrates all these observations has been discussed in detail elsewhere24. Electrophoretic analysis cannot easily distinguish between circular oligomers, catenated oligomers and figure-8 molecules. Therefore pVH51 DNA purified from a recB recC sbcA recA strain was examined by electron microscopy. The results (Fig. 2 and Table 1) demonstrated that >95% of the oligomers observed in Fig. 1 were circular oligomers. The level of circular oligomers in recB recC sbcA recA strains was ~20-fold higher than in wild-type strains and 100-fold higher than in recA strains. Low levels of catenated oligomers (Fig. 2e) and figure-8 molecules (Fig. 2f) were also observed. To quantitate accurately the levels of figure-8 molecules present, the pVH51 DNA was converted to a mixture of X-forms (Fig. 2g, h) and linear monomers by digestion with KpnI (one cleavage site

per monomer<sup>25</sup>) in conditions that prevent branch migration<sup>15,24</sup> before mounting the DNA for electron microscopy. The results of this analysis (Table 1) verified the presence of figure-8 molecules in the DNA preparation and suggested that figure-8 recombination intermediates might function in the recombination reaction observed in recB recC sbcA recA strains.

The exact relationship between plasmid recombination and the interconversion of plasmid oligomers is unknown; thus we sought to develop a procedure that would allow a more direct measure of plasmid recombination. Tetracycline-sensitive (tetmutations of the ampicillin-resistant, tetracycline-resistant plasmid pBR322 (ref. 26) were isolated by digesting pBR322 DNA with either BamHI or SalI, filling in the resulting 'sticky ends' with reverse transcriptase, followed by cyclization in blunt end-ligation conditions. The resulting plasmids contained 4base pair (bp) insertions, inactivating the tetracycline-resistance gene and either the BamHI (pRDK2) or SalI (pRDK3) cleavage site. These tet mutations had reversion frequencies of <10 The two plasmid DNAs were then digested to unit-length linear DNA molecules using EcoRI and joined to each other with T4 DNA ligase to construct a circular dimer containing one copy of each of the two different mutant alleles in tandem repeat (pRDK301). When this plasmid DNA is transformed into a recombination-proficient E. coli strain, it should recombine to yield a functional tetracycline-resistance gene at a characteristic frequency and the production of tet' progeny during the growth of the initial tet transformant should be related to the recombination frequency. Control experiments (data not shown) demonstrated that recombination occurred to produce tet progeny and that it resulted in the rearrangement of the inactivated restriction endonuclease cleavage sites with respect to each other. The construction of these plasmids and their use in a fluctuation test27 to determine the frequency of plasmid recombination will be described in detail elsewhere. A similar assay has been used to study SV40 recombination28

To determine the effect of recombination-deficient mutations on plasmid recombination, a set of isogeneic E. coli strains containing different recombination-deficient mutations was transformed to amp with pRDK301 DNA and the production of tet' progeny measured as described in Table 2. The effect of fluctuation27 on the measurements was mitigated by making a number of independent determinations and averaging the results. The results (Table 2) showed that recombination to tet' in wild-type backgrounds (sbcA+) was reduced by recA and recF mutations but was stimulated by recB recC mutations. In contrast, recombination in recB recC sbcA strains was stimulated by recA and recF mutations. The difference in the effect of recA and recF mutations on recombination in wild-type and recB recC sbcA strains was quite striking-recombination in recB recC sbcA recA strains was 11,700 times higher than in recA strains and 500 times higher in recB recC sbcA recF strains than in recF strains. This effect required the sbcA mutation as the recA and recF mutations decreased recombination in recB recC strains. Furthermore, the suppression of recA mutations by sbcA mutations occurred in the presence of functional recB and recC genes.

These results demonstrate that plasmid recombination in wild-type E. coli requires the recA and recF gene products, which is consistent with the findings of others<sup>17,29</sup>. Note that the effect of recF mutations on plasmid recombination differs

Fig. 2 Electron microscopic analysis of pVH51 DNA purified from JC9604 recA56 recB21 recC22 sbcA23. The plasmid DNA preparation analysed in Fig. 1h was treated with y-irradiation to relax the super-twisted DNA molecules or digested with KpnI for 10 min at 10 °C (in conditions supplied by New England Biolabs). After each treatment the DNA was mounted for electron microscopy by the aqueous technique essentially as described elsewhere 13,37. The representative DNA molecules shown are: a, circular

dimer; b, circular trimer; c, circular monomer and circular tetramer; d, circular pentamer; e, catenane of two trimers; f, figure-8 containing two monomer units; and g, h, X-forms produced by KpnI digestion.

significantly from that on conjugation-mediated recombination 9.10. The effect of recB recC mutations is complex as they stimulated genetic recombination of pBR322 but not oligomerization of pVH51. These observations are not inconsistent and are due to the use of two different assays to measure recombination, as we have recently shown that the products of recombination in recB recC strains are almost exclusively circular monomers. These results suggest that the recB recC gene product (exonuclease V) is probably involved in the resolution of recombination intermediates<sup>29</sup>. We have also shown that E. coli strains containing mutations in the gene for topoisomerase I are deficient in plasmid recombination (R.A.F., R.K. and J. C. Wang, unpublished results).

Our results have demonstrated that sbcA mutations induce a recombination pathway that will catalyse plasmid recombination more efficiently than the normal wild-type recombination pathway. Interestingly, this pathway does not require functional recA and recF genes, which suggests that the mechanism of recombination catalysed by it differs considerably from wild-type recombination. Similar results, obtained in studies which examined the effect of sbcA mutations on recombination of bacteriophage  $\lambda$  red, suggest that plasmid and  $\lambda$ recombination may be similar in strains containing sbcA mutations<sup>30</sup>. Presumably, plasmid recombination in recB recC sbcA strains requires proteins coded for by the Rac cryptic prophage as well as other unidentified E. coli gene products31. We have not tested the effect of sbcB mutations on plasmid recombination as these mutations affect the ability of E. coli to maintain plasmids32

Consideration of the data available shows that the recombination-deficient mutations have different effects depending on the type of E. coli recombination event analysed 6,9,10,17,29, These observations suggest that the different homologydependent recombination events differ structurally and there-

Table 2 Effect of recombination-deficient mutations on recombination of

The *E. coli* strain of interest was transformed to ampicillin resistance with pRDK301 DNA<sup>39</sup>. A 10-ml culture of L-broth containing 50  $\mu g$  ml<sup>-1</sup> ampicillin was inoculated with an entire transformant colony and incubated at  $37^{\circ}$ C with shaking until a cell density of  $5 \times 10^{7}$  was obtained. Samples were then plated out on L-broth plates containing either  $50 \, \mu \mathrm{g} \, \mathrm{ml}^{-1}$  ampicillin or  $50 \, \mu \mathrm{g} \, \mathrm{ml}^{-1}$  ampicillin +25  $\mu \mathrm{g} \, \mathrm{ml}^{-1}$  tetracycline to determine the proportion of Tet' cells present in the culture. The values shown are the average results obtained from an analysis of 10 independent cultures. The strains tested are those described in the Fig. 1 legend, and RK1064 recA56 recB21 recC22 and RK1289 recA56, sbcA23 All are isogeneic with E. coli AB1157. ND, not determined.

fore require different proteins to catalyse them. It also seems likely that proteins like exonuclease V (the product of the recB and recC gene 35,36) may function differently in different recombination events. This could explain why recB recC mutations affect the formation of stable recombinants in topologically similar  $\lambda \times F'$  and plasmid crosses differently<sup>33</sup>. The nature of the significant differences between all these recombination events is not fully understood.

We thank Dr A. J. Clark for supplying strains, Mary Jane Doherty and Paul Morrison for technical assistance, and Judith Rawlings for help in preparing the manuscript. ## In vivo decoding rules in Schizosaccharomyces pombe are at variance with in vitro data

P. Munz\*, U. Leupold\*, P. Agris† & J. Kohli\*

\* Institute of General Microbiology, University of Bern, Bühlstrasse 24, CH-3012 Bern, Switzerland † Division of Biological Sciences, University of Missouri, Columbia, Missouri 65211, USA

On the basis of in vitro experiments, conflicting hypotheses have been proposed for the assignment of tRNA isoacceptors to the reading of synonymous codons<sup>1,2</sup>. Here we present a genetic approach for studying the decoding capacity of serine isoacceptors in vivo. Cells of Schizosaccharomyces pombe have been depleted of tRNA Ser by mutating the two genes known to code for this isoacceptor, sup3 and sup9, first to UGA nonsense suppressor alleles and then to suppressor inactive alleles carrying secondary lesions. The lethality resulting from the combination of inactive alleles at both loci indicates that tRNA Ser local is essential for growth. Disregarding the remote possibility that this tRNA has vital roles other than in protein synthesis, we conclude that its function in translating UCA cannot be taken over by any other serine tRNA, including the major inosinecontaining isoacceptor. This is at variance with both the wobble rule for inosine proposed by Crick<sup>1</sup> and the 'two out of three' reading scheme proposed by Lagerkvist<sup>2</sup>, and suggests that decoding rules deduced from in vitro data do not necessarily apply to the in vivo situation.

The wobble hypothesis of Crick states that some bases at the first anticodon position can pair with the third codon base in a non-standard way, allowing UG, GU, IU, IC and IA pairs beside the standard ones<sup>1</sup>. Experimental support for the wobble rules is provided by triplet binding assays with *Escherichia coli* ribosomes<sup>3</sup>. However, exceptions to this rule have been described: extended wobbling is observed in mitochondria where U recognizes codons ending with U, C, A and G (refs 4-6). The same seems to be true for a tRNA<sup>Gly</sup> in *Mycoplasma mycoides*<sup>7</sup>. On the other hand, some modifications of U in the wobble position have been proposed<sup>8</sup> to restrict the recognition to codons ending with A.

A further discrepancy (the subject of the present study) concerns the wobble rule for inosine. In the eukaryotes studied so far a major tRNA<sup>Ser</sup> with the anticodon IGA was found and thought to be responsible for the recognition of the codons UCU, UCC and UCA<sup>9,10</sup>. However, in Saccharomyces cerevisiae<sup>11</sup> and Schizosaccharomyces pombe<sup>12</sup> a UCA-reading tRNA<sup>Ser</sup> with the anticodon U\*GA has also been identified. We present here genetic evidence which suggests that in S. pombe, this minor isoacceptor evolved because the major serine tRNA is unable to translate UCA in vivo.

Our approach was to deplete cells of a specific active tRNA by genetic means and to observe the consequences on cell growth. The genes  $sup3^+$  and  $sup9^+$  in wild-type strains of S. pombe code for the tRNA<sup>Ser</sup> isoacceptor having the anticodon U\*GA. This is inferred from genetic evidence<sup>12</sup> and from the nucleotide sequence of the UGA-reading sup3-e opal suppressor tRNA<sup>ser</sup> (e for efficient; anticodon U\*CA, where U\* is partly 2-thiouridine and partly 5-(methoxycarbonylmethyl)-uridine)<sup>13</sup>. A corresponding situation holds for the tRNA Leu isoacceptor (anticodon U\*AA) which is coded for by the genes sup8+ and sup10<sup>+</sup>. Mutations at the anticodon site of these two genes lead to efficient opal suppressor alleles and the product of one of these (sup8-e tRNA) has been sequenced<sup>14</sup>. Strains carrying such opal suppressors thus produce either a tRNA ser or a tRNA<sup>Leu</sup> whose anticodon U\*CA no longer recognizes UCA or UUA, respectively. All four opal suppressors have been inactivated by secondary mutations that map within the respective suppressor genes at different sites 15. These secondary lesions are likely to abolish either the biosynthesis or function of the suppressor tRNAs.

By crossing strains carrying inactive suppressor alleles at, different loci, recombinants harbouring the mutant alleles at both loci can be obtained (Table 1). Three types of tetrads are observed in such crosses and they occur in frequencies expected for a two-factor cross of randomly assorting genes: 1/6 parental ditype tetrads (PD), 2/3 tetratype tetrads (T) and 1/6 nonparental ditype tetrads (NPD). The four suppressor genes studied are not linked genetically to each other. The PDs consist of four colonies. In tetratypes and NPDs, respectively, one and two recombinant spores that carry two inactivated suppressor genes coding for the same tRNA (that is, sup3-e, rX sup9-e, rX or sup8-e, rX sup10-e, rX; r for reversion) fail to form colonies on yeast extract agar. In fact they are unable to undergo the first cell division. Whereas tRNA<sup>ser</sup>-deficient spores elongate to form structures resembling a premitotic stage,  $tRNA^{\mathrm{Leu}}$ -deficient spores do not germinate at all. Identical results were obtained when the spores were placed on minimal agar supplemented with adenine (the only requirement of the strains involved) and incubated at 25°C as well as at standard 30°C (data not shown). Even when one or both partners of a cross carry an active suppressor gene (no inactivating second-site mutation present in one or both suppressor genes of a given pair), recombinants lacking wild-type alleles fail to grow. However, strains carrying two active suppressors inserting different amino acids (for example, sup3-e sup8-e) are viable 16. Thus the lethality observed in combinations of two mutated tRNA<sup>Ser</sup> genes and two mutated tRNA Leu genes, respectively, is due to the loss of the corresponding wild-type tRNAs and not due to excessive suppression.

The indispensable nature of tRNA <sup>Leu</sup><sub>UCA</sub> and tRNA <sup>Leu</sup><sub>UUA</sub> demonstrated by these results is interpreted to mean that in S. pombe, these are the only tRNAs able to read UCA and UUA, respectively with an efficiency sufficient for cell growth. The alternative explanation which assumes an essential function of the specific tRNA <sup>Leu</sup><sub>UCA</sub> and tRNA <sup>Leu</sup><sub>UUA</sub> isoacceptors in processes unrelated to protein synthesis cannot be excluded at present, but seems unlikely.

As our data indicate that in S. pombe the codon UCA is read efficiently only by the tRNA<sup>Ser</sup> with the anticodon U\*GA (a minor isoacceptor), we have purified the major tRNA<sup>Ser</sup> from this organism. We are now sequencing this tRNA and HPLC of tRNA digests<sup>17</sup> has revealed that it indeed contains inosine (our unpublished results). The lack of efficient UCA recognition by the inosine-carrying S. pombe serine tRNA is paralleled by the observation made in S. cerevisiae that no serine-inserting ochre suppressor tRNAs were found to be derived from the inosine-carrying isoacceptor<sup>11</sup>. We conclude from this that in both yeasts, wobbling of inosine when present in the first position of the anticodon IGA of the major tRNA<sup>Ser</sup> isoacceptor permits recognition of the serine UCX codons ending with U or C only.

The finding that the codon UCA is efficiently translated only by the serine tRNA containing the anticodon U\*GA also argues against decoding of the serine codon family UCX by the 'two out of three' method proposed by Lagerkvist<sup>2</sup> for those families of codons that differ only in the third position and code for a single amino acid. In this hypothesis, which is based on *in vitro* protein synthesis experiments, tRNAs pairing in a standard way at the first two codon positions are predicted to read all four codons of the family, irrespective of the nature of the wobble pair.

Similar data excluding decoding by the two out of three method have been reported for the UCG codon in S. cerevisiae, where it was demonstrated that tRNA<sup>Ser</sup> with the anticodon CGA is essential<sup>18,19</sup>. The same situation probably holds for S. pombe, as suggested by preliminary results obtained with a UGA suppressor derived from the gene coding for this tRNA (H. Amstutz, personal communication). In both yeasts the gene coding for the minor tRNA<sup>Ser</sup><sub>UCG</sub> has been sequenced<sup>11,20</sup>. Suppressors derived from it are haplo-lethal in both organisms. The essential nature of the tRNA<sup>Ser</sup> with the anticodon CGA which is demonstrated by this finding also shows that the hypermodified uridine at the wobble position of tRNA<sup>Ser</sup><sub>UCA</sub> prevents reading of the codon UCG. This agrees with earlier in

The genetic methods used are described elsewhere 15. All strains involved carried the opal nonsense mutation ade6-704 which causes an adenine requirement and the accumulation of a dark red pigment in cells grown on media containing limiting adenine concentrations (for example, yeast extract agar on which asci were dissected). Active opal suppressors (sup3-e, sup9-e, sup9-e, sup9-e and sup10-e) combined with ade6-704 give prototrophic and white colonies, but the secondarily inactivated suppressors (supX-e, rY) have no effect on the ade6-704 phenotype except in the following cases: sup3-e, r8, -r36, sup8-e, r61, -r440, -r463, sup10-e, r17 and -r24. These strains display a pink rather than dark red pigment but are nevertheless auxotrophic. The segregations of colour differences in such cases are in complete agreement with the interpretation that the lethal spores contain mutant suppressor alleles at both loci involved. A minority of tetrads displayed in addition to the spore lethality caused by tRNA depletion, a superimposed lethality of unknown nature. The two types could be distinguished by microscopic examination, as non-growers due to tRNA defects had a constant, characteristic morphology

vitro data8 which indicate that certain modifications of U in the wobble position restrict a tRNA to the recognition of codons ending in A

Further evidence against the hypothesis of two out of three reading has recently been presented by Murgola and Pagel<sup>21</sup>, who showed that in E. coli the glycine codon GGA is read in vivo only by  $tRNA^{Gly}$  with the anticodon NCC, where N is a partially modified uridine<sup>22</sup>. The finding that in S. pombe the codon UUA is read efficiently only by the tRNA Leu with the anticodon U\*AA contrasts with earlier in vitro protein synthesis data obtained for yeast and E. coli tRNA which suggested that UUA may be read by more than one leucine isoacceptor<sup>23,24</sup>

Clearly, in vivo decoding must be studied in more detail, but available evidence suggests that it does not simply conform to the hypotheses proposed on the basis of in vitro data.

We thank Dr C. W. Gehrke for help with the HPLC methods and Dr R. Egel for his hospitality to U. L. at the Institute of Genetics of the University of Copenhagen, where this study was initiated. ## Wild-type tRNA<sub>G</sub><sup>Tyr</sup> reads the TMV RNA stop codon, but Q base-modified tRNA<sub>0</sub><sup>Tyr</sup> does not

## Mariann Bienz\* & Eric Kubli

Zoological Institute, University of Zürich-Irchel, Winterthurerstrasse 190, CH-8057 Zürich, Switzerland

Although protein synthesis usually terminates when a stop codon is reached along the messenger RNA sequence, there are examples, mainly in viruses, of the stop codon being suppressed by a tRNA species. A strong candidate for this phenomenon occurs in tobacco mosaic virus (TMV) in the form of two proteins (110K and 160K, of molecular weights 110,000 and 160,000, respectively)<sup>1</sup>, sharing an N-terminus sequence, which are translated in vitro from a purified species of viral RNA. We have investigated the identity of the tRNA responsible for production of the 160K protein and show here that it is one of the tyrosine tRNAs. Another tyrosine tRNA, in which the first base of the anticodon is highly modified, does not act as a suppressor, indicating the possible regulatory function of such modifications.

As an assay system for readthrough, we have used simultaneous injection of TMV RNA and amber or ochre suppressor tRNAs from yeast into Xenopus oocytes; this results in synthesis of the 110K and 160K proteins<sup>2</sup>. In the process of screening RPC-5 fractionated Drosophila melanogaster tRNAs (21 suppressor stocks and Oregon wild type) for putative amber or ochre suppressors, we found that one fraction  $(c_1)$  contained a strong readthrough activity in every RPC-5 profile tested, including the wild type (Fig. 1a, b). The fact that this readthrough activity is contained in every tRNA preparation indicated that we had discovered a natural suppressor tRNA for the TMV RNA 110K protein stop codon. Aminoacylation shows that this RPC-5 fraction contains a tRNA Tyr isoacceptor (Fig. 1a), a good candidate for such a suppressor. Purification of this tRNA to homogeneity<sup>3</sup> and subsequent injection with TMV

Present address: MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH,

RNA unambiguously demonstrates that the synthesis of the 160K protein is stimulated proportionally as a function of the concentration of this tRNA in the oocyte (Figs 2, 3). Injection of tRNATyr isolated from yeast4 produces the same results (Figs 2, 3). This finding can also be reproduced in vitro by addition of tRNATyr to a TMV RNA-primed reticulocyte extract5. Hence tRNA Tyr acts as a natural suppressor tRNA in the production of TMV proteins and is probably responsible for the synthesis of the 160 K protein in tobacco plants as well as in in vitro and in vivo TMV RNA translation experiments where this protein has always been observed 1,6. This interpretation is supported by the fact that the readthrough protein is synthesized in different protein synthesizing systems and with different tRNA components, such as the Xenopus oocyte<sup>2,6</sup>, wheat germ and reticulocyte extracts, and TMV-infected tobacco plants, A minor tRNATyr eluting at higher NaCl concentrations from the RPC-5 column (Fig. 1) can also induce the synthesis of the readthrough protein<sup>5</sup>, but none of the following purified tRNAs could produce this effect: tRNA<sub>G</sub><sup>Asp</sup>, tRNA<sub>G</sub><sup>Asn</sup>, tRNA<sub>G</sub><sup>Glu</sup>, tRNA<sub>G</sub><sup>His</sup>, tRNA<sub>G</sub><sup>Phe</sup> and tRNA<sub>4</sub><sup>Val</sup>, all from *Drosophila*, and tRNA<sub>S</sub><sup>Ser</sup> from yeast<sup>5</sup>. Furthermore, the *Xenopus* oocyte is not sensitive to artefacts2, such as enhanced synthesis of the 160K protein by addition of spermidine or increasing the Mg<sup>2</sup> concentration10

Amber and ochre suppressor tRNA<sup>Tyr</sup> preparations contain about 1/8th suppressor tRNA<sup>Tyr</sup> and 7/8ths wild-type tRNA<sup>Tyr</sup>, reflecting the fact that only one of the eight tRNA<sup>Tyr</sup> genes present in yeast has mutated to a suppressor, and that these two kinds of tRNA cannot be separated from each other<sup>11</sup>. Hence, the readthrough induced by tRNA<sup>Tyr</sup>-derived amber or ochre suppressors is due to the superimposed effect of the suppressor tRNA<sup>Tyr</sup> and the wild-type tRNA<sup>Tyr</sup> (Fig. 3). Unambiguous and independent proof that the TMV RNA stop codon can be read by amber and ochre suppressor is provided by the finding that amber and ochre suppressor tRNA<sup>Ser</sup> induce readthrough, whereas wild-type tRNA<sup>Ser</sup> does not<sup>2,10</sup>.

TMV RNA has only been partially sequenced<sup>12</sup>. Unfortunately, the sequence in the region of the 110K protein stop codon is not known. However, there are strong indications for the presence of an amber (UAG) stop codon. Amber and ochre suppressor  $tRNA^{Tyr}$  and  $tRNA^{Ser}$  can induce readthrough in  $vitro^{2,10}$  and in the *Xenopus* oocyte<sup>2</sup>; amber tRNA shows a slightly enhanced readthrough activity compared with ochre  $tRNA^1$  (see also Fig. 3); yeast  $tRNA^{Tyr}$  can misread amber codons in a synthetic mRNA and in a  $Q_{\beta}$  coat protein amber nonsense mutant, but not in a  $Q_{\beta}$  ochre coat protein nonsense mutant<sup>13</sup>. Thus, the first two letters of the codon must be UA, and UGA is excluded.

Two other interpretations might be considered: pausing <sup>14</sup>, involving a tyrosine codon as a pseudo stop codon, and out of phase reading <sup>15</sup>. However, pausing seems improbable because termination occurs 10–20 times more frequently at this site than does elongation. Furthermore, it is not obvious why yeast amber and ochre suppressor tRNA <sup>Ser</sup> should enhance the readthrough effect<sup>2,10</sup>, as unconventional base pairing would be required in this case. Out of phase reading also seems improbable because it would lead only to a tyrosine codon (UAU) if the frame is shifted by –2 and if a XUA (Leu, Ile, Ser) codon preceded the stop codon (UXX). It also seems unlikely that the out of phase reading product and the readthrough induced by suppressors would have the same length, which is indeed what is observed<sup>2</sup>.

If an amber codon exists, translation by a wild-type tRNA<sup>Tyr</sup> necessitates a G-G pairing at the third position of the codon, a pairing which is forbidden by the wobble rules<sup>16</sup>. Thus, our results suggest that only the first two bases are relevant for reading through the TMV RNA stop codon, similar to the 'two out of three' reading proposed by Lagerkvist<sup>17</sup>. However, Lagerkvist's hypothesis excludes codons of the UA family from this kind of ambiguous reading.

Drosophila melanogaster contains two major tRNA<sup>Tyr</sup> isoacceptors<sup>18</sup> (Fig. 1a) which are probably homogeneic and only differ in the presence or absence of the highly modified base Q in the first position of the anticodon<sup>19</sup>. The full sequence of these isoacceptors has not yet been determined, although preliminary sequencing data confirm this assumption (W. Brunner, M. Altwegg and E. K., unpublished). The  $tRNA_Q^{Vr}$ -containing RPC-5 fraction ( $b_2$ ) does not stimulate the synthesis of the 160K protein (Figs 1-3). Only very high concentrations of  $tRNA_Q^{Vr}$  are able to increase the level of the 160K protein slightly above background (Fig. 3). The presence or absence of the Q base modification does not affect the rate or extent of protein synthesis in  $vitro^{20}$ . The  $tRNA_Q^{Vr}$  used in this experiment has not been inactivated (for example, by a nick in the anticodon) because only a single band in the tRNA region can be observed on a 7 M urea polyacrylamide gel<sup>3</sup>. Thus, degree of  $tRNA_Q^{Tvr}$  modification in the first position of the anticodon regulates the synthesis of the 160K protein.

The fact that eukaryotic tyrosine tRNA is the only one out of 170 sequenced tRNAs that possesses a modified nucleotide in the second letter of the anticodon<sup>21</sup>, a favourable codon context<sup>22-26</sup> and the secondary structure of the TMV RNA

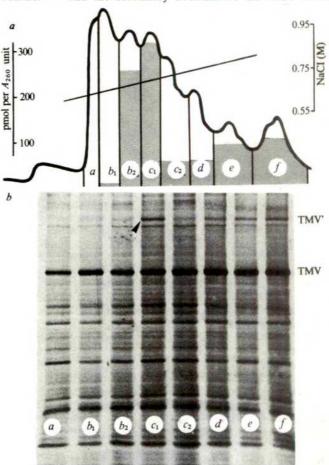

Fig. 1 Correlation of tyrosine acceptor and readthrough activities of RPC-5 fractions. A, Absorption profile (A<sub>260</sub>) of a RPC-5 chromatography<sup>31</sup> (gradient 0.55–0.90 M NaCl) of 200 A<sub>260</sub> units of crude wild-type Drosophila tRNA. The tRNA<sup>Tyr</sup> content of fractions a-f was determined by aminoacylation with <sup>14</sup>C-tyrosine<sup>19</sup> (shaded area, given in pmol per A<sub>260</sub> unit). The two major tRNA<sup>Tyr</sup> isoacceptors are localized in fraction b<sub>2</sub> (tRNA<sub>O</sub><sup>Tyr</sup>) and c<sub>1</sub> (tRNA<sub>O</sub><sup>Tyr</sup>), respectively. A minor tRNA<sup>Tyr</sup> isoacceptor is found in fractions e and f. B, Autoradiography of a 7.5% SDS-polyacrylamide gel of <sup>35</sup>S-methionine-labelled Xenopus laevis oocyte proteins after injection of TMV RNA and RPC-5 fractions a-f. The probes were precipitated with ethanol after RPC-5 chromatography, dissolved in 0.1 M Na acetate and reprecipitated with ethanol to remove the salt. The tRNA concentration injected per oocyte was 0.6–1.2 μg, the TMV RNA concentration 100 ng. At least seven oocytes were injected for each tRNA fraction. Labelling with <sup>35</sup>S-methionine, extraction of the proteins and SDS-polyacrylamide gel electrophoresis was done as described earlier<sup>2</sup>. TMV = 110K TMV protein; TMV = 160K TMV readthrough protein. Readthrough activity above background level is found in fraction ε<sub>1</sub> containing tRNA<sub>O</sub><sup>Tyr</sup> (anticodon GΨA). Fraction b<sub>2</sub> containing the Q base-modified tRNA<sub>O</sub><sup>Tyr</sup> (anticodon GΨA) isoacceptor does not induce readthrough above background level. A slight increase of readthrough activity is associated with the minor tRNA<sup>Tyr</sup> isoacceptor in fractions e and f.

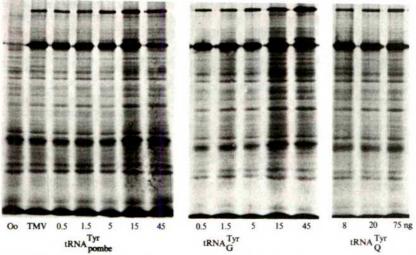

Fig. 2 Autoradiography of 7.5% 5D5-polyacy of 35M-methionine-labelled *Xenopus* oocyte proteins after tRNATyr isolated from Schizosaccharomyces pombe and D. melanogaster respectively. Experimental procedures are as described in Fig. 1 legend. Synthesis of the 160K TMV readthrough protein is stimulated proportionally as a function of the concentration per oocyte of  $tRNA_{pombe}^{Tyr}$  or  $tRNA_{qombe}^{Tyr}$  (anticodons  $G\Psi A$ ) isolated from  $Drosophila^3$ , respectively, whereas  $tRNA_{qombe}^{Tyr}$  (anticodon  $Q\Psi A$ ) isolated from  $Drosophila^3$  is unable to induce this readthrough event. All three tRNAs were at least 95% pure3.

might contribute to production of appreciable amounts of the 160K protein. These circumstances might also be responsible for the approximately equal efficiency in the reading of the TMV RNA stop codon by wild-type tRNA<sup>Tyr</sup> and amber or ochre suppressor tRNA<sup>Tyr</sup> (Fig. 3 and ref. 2). From the above we conclude that the leakiness of the TMV RNA stop codon is due to the misreading of an amber stop codon by a wild-type tRNATyr. This is analogous to readthrough of the UGA termination codon of the coat protein of phage QB, thus producing a product indispensable for infection in Escherichia coli<sup>27-29</sup>

Geller and Rich30 have proposed that the readthrough phenomenon might represent a control of gene expression at the level of termination. They pose the question of whether readthrough of certain proteins occurs, for example, in certain developmental stages of an organism, or after transformation of cells. In fact, significant changes can be observed in the extent of Q base modification in tRNAs isolated from different ontogenetic stages in D. melanogaster 19,31. In transformed mammalian cells the Q base modification disappears almost completely<sup>32</sup>. Whether these changes reflect any activities, as suggested by Geller and Rich<sup>30</sup>, is not known. Putative changes in the extent of Q base modification of the tRNAs in TMVinfected tobacco plants have yet to be demonstrated. Thus, gene expression could be regulated by a single modification enzyme.

We thank Drs B. Marcum, J. Kohli, B. Strehler and D. Zimmern for critically reading the manuscript, Drs P. J. G. Butler and J. D. Smith for providing TMV virus and yeast amber and ochre suppressor strains respectively, and EMBO for providing a short-term fellowship to M.B. during which this work was initiated. This work was supported by Swiss NSF grant 3.579-0.79 and the Hescheler Stiftung.

## E. coli ribosomal protein L10 inhibits translation of L10 and L7/L12 mRNAs by acting at a single site

## J. L. Yates, D. Dean, W. A. Strycharz & M. Nomura

Institute for Enzyme Research and Departments of Biochemistry and Genetics, University of Wisconsin, Madison, Wisconsin 53706, USA

The genes coding for ribosomal proteins L10 and L7/L12 and for the subunits for RNA polymerase  $\beta$  and  $\beta'$  are clustered within the same transcription unit ( $\beta$  operon) located at the 88-min region of the Escherichia coli genome 1,2. The regulation of these genes is of particular interest because of the ratio of synthesis of the proteins (copy ratio L10:L7/L12: $\beta$ : $\beta'$ = 1:≥4: 0.2: 0.2) and because synthesis of the ribosomal proteins and of  $\beta$  and  $\beta'$  is apparently subject to different regulatory signals (see ref. 3 for a review). It was previously shown that certain ribosomal proteins, including L10, can inhibit the translation of their own mRNA and of mRNA of other genes from the same transcription unit<sup>4-11</sup>. This regulation is physiologically significant in coordinating the synthesis of ribosomal proteins and ribosomes. Although L10 was previously shown to inhibit its own translation in vitro5, the mechanisms for regulation of L7/L12 synthesis have remained unknown. We report here the results of in vivo and in vitro investigations demonstrating that L10 regulates L7/L12 synthesis, as well as its own synthesis, by acting near the L10 translational start site.

1 08

0.94

0 99

We examined the feedback regulatory properties of L10 in vitro using a DNA-directed protein synthesizing system with various DNA templates containing all or portions of the  $\beta$ operon (Fig. 1). When a template containing the entire  $\beta$  operon  $(\lambda rif^{d}18)$  was used, addition of purified L10 to in vitro reaction mixtures specifically inhibited synthesis of L10 and L7/L12 but did not inhibit synthesis of  $\beta$  and  $\beta'$  or of any other protein (Fig. 2, lanes 1-4; Table 1). By transcribing λrif<sup>d</sup>18 DNA, extracting the mRNA and then using the mRNA to direct protein synthesis, we found, as have others<sup>5</sup>, that the inhibition by L10 occurs at the level of mRNA translation (data not shown). When a HindIII DNA fragment containing only the distal portion of the L10 gene, the entire L7/L12 gene and a proximal portion of the  $\beta$  gene was used to direct protein synthesis, addition of L10 did not affect the synthesis of L7/L12 (Fig. 2, lanes 5, 6). We therefore conclude that L10 acts at a single site and inhibits both L10 and L7/L12 synthesis and that this site is in the promoterproximal portion of the  $\beta$ -operon transcript.

When a template (pN01525) containing the entire L10 structural gene and only a portion of the L10 leader sequence was used to direct L10 synthesis, addition of L10 caused marked inhibition of L10 synthesis (Table 1). This result indicates that the 5'-proximal 186 nucleotides of the mRNA are not essential for the repressor action of L10. Using two additional DNA templates, it was also demonstrated that the repressor action of L10 does not require the presence of the distal portion of the L10 cistron. The template  $\lambda\beta$ -trp-lac1, made up of DNA of a hybrid 'trp-lac'  $\lambda$  phage carrying the  $\beta$ -operon promoter and the proximal portion of the L10 gene fused in phase to the distal portion of the trpB gene, directed synthesis of an L10-trpB fusion protein; the synthesis was specifically inhibited by L10 (Table 1). Similarly, specific inhibitory action of L10 was demonstrated using an in vitro system in which the synthesis of an L10-β-lactamase fusion protein was directed by a plasmid DNA template, pFM20, that includes the promoter and only the proximal portion of the L10 gene fused in phase to the  $\beta$ lactamase gene. These results, summarized in Table 1, imply that the target site for L10 repressor action is located between a portion of the L10 leader sequences and the proximal portion of the L10 gene, as shown in Fig. 1. This region includes a possible stem—loop structure in the leader mRNA<sup>12</sup> containing four point mutations<sup>13</sup> that prevent L10 synthesis and which were thought to be involved in the feedback regulatory mechanism for regulation of L10 synthesis. However, two such mutants are in a portion of the leader sequence (at positions 1,515 and 1,516) not required for feedback inhibition. Using a similar in vitro system, Brot et al.<sup>5</sup> found that L10 inhibited translation of L10

Fig. 1 Genes carried by  $\lambda nf^{*1}18$  and construction of plasmids used in this study. The hatched regions of  $\lambda nf^{*1}18$  represent  $\lambda$  DNA and the open regions bacterial DNA. Some of the bacterial transcription units are indicated above  $\lambda nf^{*1}18$  as a P (promoter) and a horizontal arrow indicating the direction of transcription. Transcription of the  $\beta$  operon mitiates approximately at position 1,348 (±1) (ref. 12) Below  $\lambda nf^{*1}18$  is an expanded portion of the transducing phase that denotes the relevant bacterial region. Various restriction enzyme sites are indicated below the expanded region. Only the restriction enzyme sites relevant to the present study are indicated. The complete DNA sequence of this region has been determined and can be found in refs 12, 22. The numbers below the vertical arrows

representing restriction enzyme sites indicate the nucleotide position of the restriction enzyme cut using the numbering system of ref. 12. Various portions of λrh\*18 were used to construct hybrid plasmids (shown in the figure) that carry regions of the L11 and β operons. Some of the restriction sites are shown on the plasmids so that the cloned region can be compared with λrh\*18. Plasmid pNO2020 is a derivative of pVH51 (ref. 23) and contains two copies of an EcoRI fragment (nucleotides 2,444-3,524) from λrh\*18 and one copy of another EcoRI fragment from λrh\*18 (nucleotides 2,444-3,524). For m stro studies, the Hhedilli fragment that contains the L7/L12 gene was purified from pNO2020 and used to direct protein synthesis. Plasmid pRZ4006 was used as the parental plasmid for construction of pNO1525. The plasmid pRZ4006 was constructed by K. Bertrand and is a derivative of pBR322 which has the BamHI-EcoRI fragment from pBR322 replaced with a 204-base pair (bp) Hasill fragment that contains the lac operator and promoter (personal communication). Both the BamHI and EcoRI sites were retained in pRZ4006 and transcription originating from the lac promoter is directed towards the BamHI site. The plasmid pNO1525 was constructed by digesting pRZ4006 with BamHI, treatment with DNA polymerase I and ligation with the Hasill fragment containing the L10 gene purified from λrh\*18. The resulting plasmid places the synthesis of plasmid-encoded L10 under the control of the lac regulatory elements. Plasmid pFM20 was constructed by ligating PxII-digested pBR322 to a PxII fragment (nucleotides 873-1,795) derived from λrh\*18. Plasmid pFM20 contains the β promoter and a portion of the L10 gene fused in phase' to the β-lactamase gene (bla) contained on pBR322 (ref. 24). Plasmid pGBΔBR2 was constructed by G. Barry and is described in ref. 17. The site for repressor action by L10 is indicated by a thick bar below the restriction enzyme site arrows.

Proteins were synthesized as described in Fig. 2 legend in the presence and absence of 1.9  $\mu$ M L10. Synthesis of L10 and L7/L12 from  $\lambda nf^{41}8$  and synthesis of L10 from pNO1525 were determined by immunoprecipitation followed by gel electrophoresis. Synthesis of all other proteins were determined directly by gel electrophoresis. Fluorograms made using prefisshed film were scanned with a Joyce-Loebi densitometer. Ratios of amounts of synthesis obtained in the presence of L10 to synthesis obtained in its absence are shown Proteins listed as 'control' proteins for each template are:  $\lambda nf^{41}8$ ,  $\beta B'$ ; pNO1525,  $\beta$ -lactamase;  $\lambda B$ -try-lac1,  $\beta$ -galactosidsse; pFM20, a 35,000-molecular weight  $\beta$ -lactamase-L1 fusion protein containing the N-terminus of  $\beta$ -lactamase and the C-terminus of L1.

\*For  $\lambda\beta$ -trp-lac1 and pFM20, synthesis of the L10-trpB and L10- $\beta$ -lactamase fusion proteins was measured. The proteins of molecular weights 57,000 and 13,000 respectively were identified using anti-L10 antisera.

† $\lambda\beta$ -trp-lec1 was constructed by H de Boer by fusing the HmdIII-EcoRI fragment of  $\lambda$ rrf\*18 containing the  $\beta$  promoter (nucleotides 280-2, 154 in Fig. 1) to the left arm of HindIII-digested 'trp-lec' phage  $\lambda$  RS205-7 and to the right arm of EcoRI-digested  $\lambda$  phage 459. This method has been described for other ribosomal promoters\*7. The HindIII cleavage site in the trpB gene\*\* is in the same reading frame as the HindIII site in the L10 gene.

mRNA but had "little or no effect" on L7/L12 synthesis. We obtained maximal inhibition of L7/L12 synthesis by incubating the reaction mixtures at 30 °C. At 37 °C, our results were more similar to those of Brot et al., showing only 20–30% maximal specific inhibition of L7/L12 synthesis by L10 (data not shown). We believe that our results obtained in vitro at 30 °C reflect regulation in vivo because of the following results in vivo.

A complex containing four molecules of L7/L12 and one molecule of L10, which is formed on or off the ribosome <sup>14,15</sup>, will inhibit the *in vitro* synthesis of both L10 and L7/L12 by ~50% <sup>16</sup>. We have isolated the L10-L7/L12 complex and found its *in vitro* regulatory properties identical to those of L10 alone (data not shown). Thus, the inhibition of synthesis of L10 and L7/L12 by the complex must be due to the L10 within it. The same conclusion was reached by M. Johnson, T. Christensen and N. P. Fiil (personal communication). Interaction of L10 with the target on the mRNA seems to involve the part of L10 which interacts with 23S rRNA, and not the part that interacts with the four molecules of L7/L12.

To confirm that the regulatory properties observed for L10 in vitro reflect its regulatory role in vivo, the effect of over-

Fig. 2 Inhibition of in vitro synthesis of L10 and L7/L12 by addition of purified L10, L10 purified by phosphocellulose chromatography25 starting with a 1 M NH<sub>4</sub>Cl/50% EtOH wash of 70S ribosomes depleted of L7/L12 (ref. 26). L10 was stored in 6 M urea, 50 mM methylamine phosphate pH 6.5 at -70 °C. For use in in vitro experiments an aliquot of L10 (0.72 μg ml<sup>-1</sup>) was supplemented with bovine serum albumin (BSA; 1.0 mg ml and dialysed first against 0.5 M KCl/4 M urea/2 mM potassium phosphate pH 6.5/1 mM dithiothreitol and then against KUP buffer (1.0 M KCI/1 M urea/2 mM potassium phos-phate pH 6.5/1 mM dithiothreitol). In vitro reaction mixtures (40 µl) received either 2 μl of the resulting L10 solution (lanes 2, 4, 6) or 2 µl of

110

KUP buffer containing 1 mg ml<sup>-1</sup> BSA (lanes 1, 3, 5). Proteins were synthesized in the presence of <sup>35</sup>S-methionine using 0.0017 μM λrif<sup>d</sup>18 DNA (lanes 1-4) or 0.009 µM HindIII 1,700-bp fragment (lanes 5, 6) as template, as described previously<sup>19</sup> except that incubation was for 2 h at 30 °C. The HindIII 1,700-bp fragment was prepared from pNO2020 (see Fig. 1). After incubations were completed, L10 was added to samples 1, 3 and 5. Reaction mixtures were analysed either directly by gel electrophoresis on a 13% polyacrylamide-SDS gel (lanes 5, 6) or by immunoprecipitation using rabbit anti-L10 antisera (lanes 1, 2) or anti-L7/L12 antisera (lanes 3, 4) followed by gel electrophoresis and fluorography19. A fluorogram is

production of L10 in vivo was examined. The HaeIII restriction enzyme fragment that contains the entire L10 gene and a small portion of the L7/L12 gene was inserted into a plasmid vector containing the lac operator and promoter so that synthesis of L10 was controlled by lac regulatory elements (pNO1525; see Fig. 1). The synthesis of L10 was stimulated by the addition of isopropyl thio- $\beta$ -galactoside, an inducer of the *lac* operon, in a strain which harbours the recombinant plasmid, and the synthesis rates of other individual proteins were then analysed.

The overproduction of plasmid-encoded L10 caused a marked inhibition of L7/L12 synthesis, and presumably chromosome-directed L10 synthesis, but had no effect on  $\beta$  and

Table 2 Relative synthesis rates of proteins after induction by isopropyl thio-βgalactoside or L-arabinose

	Strains					
	N02396	N02455

For labelling experiments, cells were grown in a synthetic minimal medium24 supplemented with 0.4% glycerol, all amino acids (except methionine and lysine) at 50 µg ml<sup>-1</sup> and thiamine at 2 µg ml<sup>-1</sup>. Cells were grown at 37 °C to 2 × 10<sup>8</sup> per ml. Samples of cells were pulse-labelled with <sup>3</sup>H-lysine (646 pmol ml<sup>-1</sup>; 80.5 Ci mmol<sup>-1</sup>) for 1 min followed by a 1-min 'chase' with excess nonradioactive lysine. Cells were labelled before (control cells) and 10 min after addition of isopropyl thio-β-galactoside to 1 mM or 0.2% L-arabinose, depending on the strain used (experimental cells). Cells were rapidly chilled and then mixed with a suitable amount of <sup>14</sup>C-lysine-labelled carrier cells. <sup>14</sup>C-labelled cells were prepared by growing cells in the presence of <sup>14</sup>C-lysine for several generations. Ribosomal proteins were extracted and separated by two-dimensional gel electrophoresis<sup>30</sup>. The  $\beta$  and  $\beta'$  subunits were resolved from other proteins by SDS slab gel electrophoresis<sup>31</sup>. After staining the gels, the spots corresponding to the indicated ribosomal proteins were extracted, the gels oxidized with a Packard sample oxidizer and <sup>3</sup>H and <sup>14</sup>C measured separately. The <sup>3</sup>H/<sup>14</sup>C ratio in each protein in the experimental cells was then compared with that in control cells using  $[^3H/^{14}C]$  in protein i in experimental cells the expression:

[3H/14C] in protein i in control cells

The ratios obtained were then normalized to the ratio obtained for total cellular protein. Values given are the average of two independent experiments.

\* Values significantly different from 1.0.

β' synthesis (Table 2). The inhibition of L7/L12 synthesis was due only to L10 overproduction because no such inhibition was observed when the strain carried a deletion within the plasmidencoded L10 gene (data not shown). To test for a possible in vivo regulatory role of L7/L12, we used plasmid pGBΔBR2 which has L7/L12 gene expression under control of ara regulatory elements17. Addition of L-arabinose to a strain harbouring the hybrid plasmid caused an eight- to ninefold increase in the rate of L7/L12 synthesis but did not affect that of L10 or  $\beta$  and  $\beta'$ (Table 2). (We and others<sup>5</sup>, observed that in the in vitro system, purified L7/L12 does not inhibit synthesis of L10 or of L7/L12. We therefore conclude that L10 and L7/L12 are in a translational unit regulated by L10.)

How might L7/L12 synthesis be repressed by L10 acting at the L10 translational start site? One possible explanation is that efficient translation of L7/L12 mRNA requires the translation of the preceding L10 mRNA and that the inhibition of L7/L12 synthesis by L10 is a consequence of the inhibition of L10 synthesis by L10. Such 'translational coupling' has been observed in both the trp operon 18 and the L11 ribosomal protein operon19. Ribosomal proteins seem to be synthesized from other operons in units of translational regulation with the feedback repressors acting at single mRNA target sites. We have previously suggested a mechanism of sequential mRNA translation to account for the co-regulation and equimolar synthesis of ribosomal proteins in these regulatory units19. L7/L12 differs from other ribosomal proteins in that its synthesis is at least four times faster. We suggest that translation of L10 mRNA by a ribosome 'opens' the structure of L7/L12 mRNA initiation site. allowing other ribosomes to initiate the translation of L7/L12 at least four times as efficiently as that of L10 mRNA. We might expect that, without independent feedback regulation of L7/L12 synthesis by itself, more than the four copies of L7/L12 needed per ribosome might always be synthesized. In fact there are reports that, unlike other ribosomal proteins, significant amounts of L7/L12 exist in cells as free proteins 20,21. Regardless of the exact stoichiometry of the rates of L7/L12 synthesis relative to L10, the present work suggests a mechanism for the co-regulation of the synthesis of L7/L12 and L10.

We thank G. Baughman, D. Marquis, G. Barry and K. Bertrand for plasmids; and K. Bergsland for technical help. ## **QUATERNARY SCIENCE REVIEWS**

Editor-in-Chief: D Q Bowen, Department of Geography, University College of Wales at Aberystwyth, Wales

Contributions will include systematic reviews of progress or techniques on given topics written for both specialists and other Quaternary workers wishing to keep abreast of recent developments in this multidisciplinary field for a given continent or smaller area. Shorter items will include communications about meetings and news of research group activities.

Published quarterly Annual subscription (1982) Two-year rate (1982/83)

First issue due Winter 1981/82 US\$ 70.00

US\$133.00

## CONTINENTAL SHELF RESEARCH

Editors: M Collins, University College, Swansea, UK and R W Sternberg, University of Washington, Seattle, Washington,

Articles will feature the results of fundamental and original research in physical oceanography, chemistry, ecology, sedimentology, etc. as well as more applied aspects of continental shelf research. Emphasis will be on interdisciplinary process-orientated contributions and the results of innovative experimental studies with more general applicability. Occasional review articles and a section on notes, instrumentation and methods will be included.

## Eureka! No mystique to creative thinking

## Stuart Sutherland

EVERYBODY, from Arthur Koestler to Edward de Bono, knows that there is something very mysterious about creative thinking. To achieve it one must allow one's unconscious mind to work in unusual ways in order to produce that sudden insight that prompted Archimedes to leap from his bath and startle the citizens of Syracuse by running naked through the streets. Unfortunately, the fact that these thought processes cannot be specified has not stopped Arthur Koestler and others of his ilk from writing about them at length and giving them a variety of curious names such as biassociative, Janusian, paleological, homeospatial, divergent and lateral thought. In The Mind's Best Work, David Perkins debunks the mystery of creation. Just as a great athlete uses the same muscles as the puniest individual, so the great creators use the same mundane thought processes that mediate everyday existence. To prove his point he draws not merely on the intellectual biographies of such men as Darwin and Coleridge, but on a variety of ingenious experiments undertaken by himself and others, backed up by a series of demonstrations that the reader can try out on himself.

Two of the thought processes common in creative thinking are recognition and noticing. In seeking for a difficult proof, the mathematician may recognize a similarity between the structure of the problem and that of one for which there is an existing proof, thus suggesting a method of approaching the problem. Noticing occurs when some relevant feature of a problem is detected without any conscious attempt to discover it. Just as a woman interested in fashion may notice a flaw in a new costume, so the poet may notice that a word or phrase he has written is weak. What is noticed depends very much on one's interests and knowledge. The mind has a remarkable power to recover from memory items that satisfy very diverse criteria. Anyone can recover from memory the name of a food that is white and soft and whose name begins with an "s", even though he has never been confronted with this combination of criteria before. In the same way someone working on a new problem with particular criteria for solution may discover an answer that will be regarded as original.

Perkins's own research, in which he obtained protocols of subjects' thought

The Mind's Best Work. By D.N. Perkins. Pp.368. ISBN 0-674-57627-6. (Harvard University Press: 1981.) \$18.50, £12.95.

processes whilst solving problems, suggests that the mind rarely takes great leaps. It proceeds in a step-by-step fashion through successive acts of recognition and noticing which lead towards a solution. Where a sudden leap is taken, it is because through practice on a particular type of problem someone has learned to recognize a larger pattern that is of significance.

Moreover, creative thought is not wayward — there is a reason for each step taken. The reason can usually be articulated, but not always. In everyday life we may recognize that a friend is looking morose without being able to specify what aspect of his demeanour the judgement is based upon. All creative activity involves noticing flaws, and Perkins found that good painters and poets were better than poor ones at articulating what was wrong with an unfinished work. A gut feeling that something is wrong is less help in putting it right than an ability to specify the nature of the flaw and thus to establish criteria for how to go about improving it.

The role of incubation in the unconscious mind has, according to Perkins, been overplayed. Where it helps - and there is evidence to suggest that it rarely does - it probably does so for one of two reasons. First, one of the main obstacles to solving a problem is the difficulty in giving up a particular approach which is not paying off. A respite from thinking about a problem may make it easier to try a new approach. Second, whilst someone is thinking of something else, he may be lucky enough to encounter a useful hint that could not readily be obtained in the course of a frontal attack. In just this way, Malthus's essay on population gave Darwin the clue he needed to suggest the survival of the fittest as the selective mechanism in evolution. Laboratory experiments clearly establish the importance of such hints, many of which are used by subjects without their being aware that any hint has been

Creativity in a particular field depends, of course, on a thorough knowledge of it and on practice in existing techniques.

Abstraction plays an important role people must learn that a heuristic that has been found to solve one problem may be used to solve similar problems. Again, the more the heuristics are articulated the more helpful they are. In one experiment, a group of students in a class on integral calculus were shown how the use of five heuristics could help in solving sample problems. A second group were shown how to solve the same initial set of problems, but no effort was made to emphasize the generality of the heuristics used. In testing on further problems, the former group solved twice as many as the latter

In considering the question of what makes someone creative. Perkins points out that the obvious answer is usually ignored. An important element in creativity is the desire to be creative; one can set oneself to reject the obvious and to search for new solutions to a problem. The standards people set themselves in solving problems can be all important for the solutions they produce. Subjects urged to suggest "a good title for a novel" whose plot they had been given gave solutions that were markedly inferior to those produced by subjects urged to provide "an imaginative, creative or unusual title for this plot". There is also evidence that artists and poets think critically about their own work and a willingness to accept criticism from others correlates with the quality of their achievement. Art students who were open to criticism were found a few years later to be more successful than those who rejected it, though this particular experiment may only show that an artist who wants to please his public will sell more paintings than one who does not care what the public thinks. Because of the importance of self-criticism, geniuses are not necessarily fluent: Beethoven composed with painful deliberation. One of Perkins's more curious findings is that the average rate of composition of pentameters by both good and bad poets is half a line a minute and he claims that even Byron, reputedly one of the most fluent poets, did not exceed this rate in writing The Corsair. But if fluency is not a necessity for creation, luck often is. The man must be nicely matched to the problem. Einstein's intolerance for contradictions motivated the special theory of relativity, but the very same trait led him to waste his later years seeking an alternative to quantum theory.

It has only been possible here to sketch the nature of Dr Perkins's approach to creativity. He develops the points I have made in much more detail and makes many other illuminating suggestions. Although scholarly, his book is intended for the general public and is easy to read; it has only two faults — a tendency to write down to the reader and the inclusion of some singularly unattractive line drawings, which have little relevance to the text and serve to demonstrate only that not all artists are creative. He is of course aware

that reducing the thought processes of creativity to those employed in everyday life does not explain the nature of those thought processes. But this reduction is a good beginning if only because it frees psychologists to get on with the task of explaining ordinary thought processes, and may help to stop other authors from continuing the existing tradition of producing turgid and obscure tomes on the mysteries of creation.

Stuart Sutherland is Director of the Centre for Research on Perception and Cognition at the University of Sussex.

## Contradictions in theoretical chemistry

H.C. Longuet-Higgins

Chemistry, Quantum Mechanics and Reductionism. By Hans Primas. Pp.451. ISBN 3-540-10696-0. (Springer-Verlag: 1981.) DM 68, \$32.40.

"THE purpose of this book" writes Professor Primas "is to provide a deeper insight into the modern theories of molecular matter. It . . . is not meant to be a textbook; in many respects it has complementary goals. For good and bad reasons, most textbooks ignore the historical and philosophical aspects [of theoretical chemistry] and go ahead on the basis of crude simplifications; many even lie like the Devil and do not shrink from naive indoctrination".

Remarks such as these are well calculated, as the author intends, to ruffle the placid waters of theoretical chemistry. It is difficult enough, in all conscience, to explain the technicalities of quantum chemistry to lively young minds without having one's authority undermined by pronouncements such as "the theoretical basis of chemistry and biology is not safely in our hands". From a scientist of less achievement than Professor Primas such an assertion might well be greeted with open hostility in the community of theoretical chemists. How can it be reconciled with our evident ability to compute, with greater and greater accuracy, the dissociation energies, dipole moments, force constants and other properties of molecules? If the Schrödinger equation is not good enough for Professor Primas, has he a better one to propose?

Such a reaction to the opening pages of Chemistry, Quantum Mechanics and Reductionism would entirely miss the author's point. Anyone who has studied and taught theoretical chemistry for any length of time will know how difficult it is

The latest supplement to A Bibliography of Ab Initio Molecular Wave Functions by W.G. Richards et al. has just been published by Oxford University Press. Covering the years 1978–1980, the book costs £35.

to reconcile, in his own mind and the minds of his students, the elusive properties of sub-atomic particles with the evident permanence of large molecules and crystals. There is an almost irresistible temptation to suppose, and to imply, that there is one set of laws for the very small and another for the large — a proposition which is in flat contradiction with the orthodox interpretation of quantum mechanics. Professor Primas asserts that

The mode of activity exhibited by contemporary science strikingly reminds one of what Shapiro (1965) has called the paranoid style. It is characteristic of this style that bridges between related problems are broken down so that things remain neatly and rigidly separated. Scientists who cultivate a paranoid research style are usually extremely acute and intense, show an exorbitant respect for compartmentalisation and computers, and firmly demand complete autonomy for their narrowly fixed ideas . . . The separation of philosophy and science has led to the so-called restricted world view and to the blindness of many experts who are entirely unaware of the abstract and isolating nature of modern science.

No, these are not the ravings of a iconoclast; in this long and fascinating book (it runs to over 400 pages) the author reveals a deep understanding and appreciation of the most difficult problems of quantum mechanics and of the acute paradoxes associated with its interpretation - or rather, with those alternative interpretations which do not violate experimental fact. He reveals himself as a master not only of the mathematics but also of the philosophy of science, and as a man who cares passionately about intellectual integrity, in the widest possible sense of that word. The book is uncompromisingly difficult, in an area where compromise would be unforgivable; but it is spiced with good plain questions of an acutely embarrassing kind: "What is quantum mechanics about?" "What is a classical description?" "Do isolated quantal systems exist at all?" "Does quantum mechanics apply to large molecular systems?" and so on. I wonder how

most theoretical chemists would answer these questions if some bright student were tiresome enough to ask them!

Chemistry, Quantum Mechanics and Reductionism is Professor Primas's own very positive contribution to the solution of some of these problems. The bestknown fully-developed interpretation of quantum mechanics is that of von Neumann, London and Bauer, and from this Professor Primas wants to remove just one unproved axiom, namely the universal validity of the superposition principle. He develops an alternative interpretation of his own, based on sophisticated algebraic concepts, of which the most important is that of a "W\*-algebra". To master his ideas would obviously take much time and thought, but they are logically compatible (as the orthodox interpretation is not) with the attribution of "classical" properties to molecules - an assumption which all theoretical chemists use without apology when referring to the charge, the mass or the structure of an ordinary molecule. The book may be difficult, but it is quite unusually honest and thoughtful, and is likely to prove an invaluable antidote to the narrowness of outlook which is so often apparent in chemical theorizing.

H.C. Longuet-Higgins is Royal Society Research Professor at the University of Sussex.

## Crucial colonization

**Barry Cox** 

The Terrestrial Environment and the Origin of Land Vertebrates. The Systematics Association Special Volume, No. 15. Edited by A.L. Panchen. Pp.633. ISBN 0-12-544780-9. (Academic: 1981.) £38, \$91.50.

The earliest known tetrapods are the ichthyostegid amphibians, now known from Late Devonian rocks in both Greenland and Australia. From this beginning sprang a variety of larger "labyrinthodont" amphibians, apparently ancestral to the reptiles, as well as the smaller "lepospondyl" amphibians. The transformation of our interpretation of palaeogeography, as well as progress in such fields as Palaeozoic floras and both invertebrate and vertebrate faunas, makes this a timely volume. The 20 papers were originally given at a symposium in Newcastle upon Tyne in April 1979, which was organized by Alec Panchen, editor of

Two of the papers are concerned with the geography of the world in which the first tetrapods evolved. Tarling analyses palaeomagnetic data and provides a series of continental reconstructions for the Early Devonian to Late Permian; he

suggests that China may have provided a link between Australia and Euramerica. The relationship between the changing Carboniferous geographies and the dispersal of early tetrapods is discussed by Johnson.

Two other papers deal with Palaeozoic botany. Dianne Edwards considers the appearance, habits and affinities of early vascular plants, but concludes sadly that little progress has been made in reconstructing the details of terrestrial plant communities of Devonian times, while Scott reviews the ecology of Late Palaeozoic floras, emphasizing the innovative effects of the evolution of arborescence and seed production. The only other non-vertebrate contribution is that by Rolfe, who describes the early invertebrate terrestrial faunas; these were dominated by arthropods, the larger of which, together with the amphibious eurypterids and scorpions, must have provided a food source for the earliest amphibians.

In one of the most interesting of the vertebrate papers, Thomson points out that there is little evidence that any of the Devonian lobe-finned fishes were primarily freshwater in habitat; he believes that the amphibians may have evolved from fish that still spent at least part of their lives in coastal lowland estuaries. But to which lobe-finned group did this fish belong? Opinions seem to be becoming more, not less, diverse. Though Rackoff's study of the fins of one osteolepid rhipidistian shows a number of close resemblances to the tetrapod limb, Janvier believes that the osteolepid pectoral girdle. though variable, could not have evolved into that of tetrapods. But an even more heretical phylogenetic idea also appeared at the symposium. Both Patterson, in an historical review of the problem of tetrapod origins, and Gardiner in a reappraisal of current evidence, suggest that the lungfish are the closest relatives of the tetrapods. The debate on this central issue promises to be interesting and fruitful.

In another morphological paper, Carroll notes the similarity between the hyomandibular of rhipidistians and that of early amphibians, and suggests that the bone retained a cheek-support function well into the Amphibia, only a few lines having independently transformed it into a sound-transmitting stapes.

Two early tetrapod faunas are reviewed. The new basal Late Carboniferous Scottish Cowdenbeath fauna is described by Smithson; it includes aquatic fish-eating and possibly herbivorous forms, as well as one genus that may have eaten terrestrial invertebrates, but provides few antecedents for later faunas. Andrew Milner makes a detailed analysis of the well-known, very diverse, later Carboniferous fauna of Nýfany, Czechoslovakia, and distinguishes its different components — open-water, shallow swamp-lake and

terrestrial-marginal endemics, as well as rarer elements from neighbouring environments.

Finally, a number of authors discuss the origin and classification of particular taxa—the anthracosaurian amphibians (Panchen), the Nectridea (Angela Milner), the Cotylosauria (Heaton), the Pelycosauria (Reisz) and the major amniote groups (Gaffney).

The contributions maintain a high

standard of interest and readability, and the volume is attractively produced; there are few typographical errors, and there is both an author and a subject index. It should serve for many years as both a benchmark of our knowledge, opinions and attitudes today, and as a source of references to the earlier literature.

Barry Cox is Professor of Zoology at King's College, University of London.

## Electron microscopy at the limits

David J. Smith

Experimental High-resolution Electron Microscopy. By J.C.H. Spence. Pp.420. ISBN 0-19-851365-8. (Clarendon/Oxford University Press: 1981.) £35, \$74.

THE technological revolution of the past decade has resulted in a concomitant improvement in the flexibility and usage of the commercially available electron microscope, not least in the direction of improved performance. Lattice and point resolutions in the region of 1Å and 3Å, respectively, have become standard. Hence, instead of high-resolution electron microscopy remaining an esoteric art, it is, in principle at least, now available to all those who can afford the admittedly considerable price of the latest instruments. That more scientists have not yet taken advantage of the opportunity to resolve physical details almost at the atomic level probably reflects the fact that recording a high-resolution micrograph, even with these advanced microscopes, is still difficult; moreover, the literature does not provide much guidance to the newcomer. This readable account of highresolution methodology thus represents a sorely needed addition to the field.

The book can be considered to consist of two parts. The first, comprised of Chapters 3 and 4, the first half of Chapter 5 and most of Chapter 6, provides a useful introduction to dynamical electron diffraction theory, setting out clearly most of the underlying concepts and in particular emphasizing the possible pitfalls of micrograph interpretation. Copious references have been included, making these chapters useful even to experienced workers. These sections are also carefully cross-referenced to the remainder of the book

On the experimental side, there are separate chapters on lenses and electron sources; much of the information here is tangential to the major theme of the book, and could well be omitted in a first reading. Nevertheless, these chapters represent valuable compilations of background material and, again, are well-referenced.

The remaining chapters deal with the practical problems involved in realizing

high-resolution micrographs, pointing out the requirements for knowledge of relevant electron-optical parameters, describing possible sources of interference and instability, and discussing operating techniques. These details will be of greatest value to the novice but many experienced workers will undoubtedly also find information of relevance to their research.

Despite the obvious attractions of the book, it is not free of some misleading or incorrect statements, and there are certainly strong arguments for re-ordering the subject matter. For example, the second half of Chapter 5, which briefly describes some applications, could well follow Chapter 10 on methods, and Chapters 1 and 2, which primarily deal with experimental details, would be better placed after the theoretical discussions of Chapter 6. The worst of the factual errors, presumably due to the publisher rather than the author, is located on the dust jacket where it is claimed that "Applications . . . are all described in full practical detail . . ." - this was manifestly not one of the author's objectives. It would also appear unlikely that any manufacturer of lathanum hexaboride cathodes would readily acquiesce to operation in vacuum levels of only "better than 10-5T" (p.262), and most users of field-emission sources would expect tip lifetimes of the order of several months, irrespective of operating voltage, rather than "about 80 hours" (p.263).

Such criticisms are obviously minor, and overall the author has produced a text which is far more than a "recipe book" for the beginner. He has evidently drawn on the wealth of knowledge of his many friends and colleagues in Oxford, Melbourne and Tempe, three of the leading centres in the field, as well as his own practical experience, and his book should become a valued guide and source of information for the practising microscopist.

David J. Smith is Director of the High Resolution Electron Microscope Project at Cambridge University.

## Fish-heads and breadcrumbs to feed the five thousand

John Rivers

Nutrition and Food Science: Present Knowledge and Utilization. Edited by Walter J. Santos et al. Three-volume set. Vol. 1, Food and Nutrition Programs and Policies, pp.850, ISBN 0-306-40342-0. Vol. 2, Nutrition Education, Food Science and Technology, pp.900, ISBN 0-306-40343-9. Vol. 3, Nutritional Biochemistry and Pathology, pp.758, ISBN 0-306-40344-7. (Plenum: 1980.) Vol. 1 \$75, £47.25; Vol. 2 \$79.50, £50.09; Vol. 3 \$69.50, £43.79. Three-volume set \$195, £122.88

Nutrition and Food Science is a weighty work: three volumes, 2,500 pages, 750,000 words. That is about as long as the Bible or the complete works of Shakespeare. It seems reasonable to ask if these three books measure up to such standards.

The answer, sadly, is no. These volumes will rarely be read, and even more rarely enjoyed. They cannot even be treated as a coherent work: they are a patchwork of 250 essays linked by the fact that their authors attended the Eleventh International Congress of Nutrition in Brazil, 1978.

The editors have given each volume a subtitle and subdivided each volume, presumably to impose some order on them, but this attempt fails. For example the title for Vol. 2, Nutrition Education, Food Science, and Technology, is in itself a portmanteau. Fittingly so, since the volume is further subdivided into four parts — Animal and Vegetable Resources for Human Feeding, Food Science and Technology, Research in Food Nutrition (sic) and Nutrition Education — and since national nutrition surveys are put in Vol. 2 even though Vol. 1 seems more appropriate.

In this electronic age the international congress is becoming an anachronism. In small fields, especially fast-moving ones, it is still a feasible and important way of communicating. But all too often congresses are only "holidays for the boys". The cliché that the best science is discussed in the bar is actually a two-edged one.

Some time ago the Economist magazine, in an article on scientific research, noted that, of the 32 participants at an international physics conference in 1927, a third were, or were to be Nobel Laureates. An equivalent meeting in 1980 had 800 participants, no Nobel prizewinners and only routine investigations were reported. The Economist should have dissected nutrition. The triennial International Nutrition Congresses have doubled in size about every ten years. The science they represent grows only one-quarter as fast, so necessarily the congresses have become less and less important as a legitimate part of scientific communication, and more and more a social event.

At the Eleventh Congress, 5,000

participants gathered together in Brazil and seem to have achieved nothing: were all those journeys really necessary? Like a somewhat more famous gathering of 5,000 they subsisted on a very meagre diet. But if a miraculous transformation of the loaves and fishes of their intellects occurred, then it must be the baskets of leftover rubbish that have been published for posterity.

For that is what this work is about. It is a three-volume commemoration of an event. There are some good, original papers, such as Jul's study on dairy farming in Calcutta, but they are few, and will probably be lost in the mound of fish-heads and breadcrumbs. A mound of papers in which nothing much is said, in which most tables

and graphs seem to be referred back to previous publications, in which representatives of commercial organizations are simply reporting the use of their products, and a collection which overall could have done with refereeing and extensive subediting.

Nutrition and Food Science is a reverberating cry for something to be done to stem the flow of paper that is dignified by the appellation "scientific literature". This is neither science nor literature.

John Rivers is a Lecturer in the Department of Human Nutrition at the London School of Hygiene and Tropical Medicine, University of London

## Depth in stability for the cognoscenti

P.H. Roberts

Hydrodynamic Stability. By P.G. Drazin and W.H. Reid, Pp.525. ISBN 0-521-22798-4. (Cambridge University Press: 1981.) £35, \$77.

"Not every solution of the equations of motion, even if it is exact, can actually occur in nature. The flows that occur in nature must not only obey the equations of fluid dynamics, but also be stable". The significance of this apt quotation from Landau and Lifshitz with which the authors of Hydrodynamic Stability open their book is evident from the scarcity in nature of simple orderly ("laminar") motions and the abundance of irregular ("turbulent") flows. The transition from the former to the latter starts with the instability of the laminar flow, a process that can be studied in controlled laboratory conditions and, with comparative ease, by theoreticians.

The achievements of stability theorists are now so extensive that the authors had to make hard decisions in limiting their text to even 525 pages. They have opted for depth, rather than breadth, of treatment, and paid particular attention to classic situations such as Bénard convection, circular (Couette) flow and plane parallel flow.

A consideration in the authors' choice of topics was probably the existence of Chandrasekhar's classic work, Hydrodynamic and Hydromagnetic Stability (Clarendon Press, 1961). Wonderful though Chandrasekhar's treatise is, it is sometimes felt today that it contains a number of lacunae: it overstresses variational methods; it ignores a useful technique (asymptotic analysis); it omits one of the oldest and possibly the mathematically most interesting of all linear stability problems, that raised by

plane Poiseuille flow; and it says little about non-linear stability. None of these points would have been fair criticism in 1961 when the book was published, but today many specialists will welcome Drazin and Reid's account, if for no better reason than because it successfully redresses the balance.

The authors are of course well known, particularly for their work on parallel flows, and it is here that readers will discover the most penetrating discussions, and the deepest and most elegant mathematics. Indeed, some may wonder whether the authors' enthusiasm has carried them too far, and whether all of the sophisticated theoretical weapons displayed are essential to their own armouries. This space might have been better used in expounding non-linear theory still further, or in providing deeper discussions of baroclinic instabilities, another subject that has exploded since Chandrasekhar wrote his book. Most readers will find the discussion of pinch instabilities frustratingly brief.

These are minor reproaches only. The work is undeniably of high scholarship, consummate accuracy and penetrating insight. Teachers of graduate courses will find the problems at the end of each chapter imaginative, but difficult: solutions can be obtained by application to either author. All specialists in stability theory will be happy that two such authorities have found the time, and spared so few pains, to produce a work of such excellence.

P.H. Roberts is Professor of Applied Mathematics at the University of Newcastle upon Tyne.

## **Energy: Present and Future Options**

edited by D. Merrick, National Coal Board, Coal Research Establishment, Cheltenham.

and R. Marshall, Department of Physics, The University, Keele This volume reviews a number of options for future energy supplies, and possible technologies for conversion and use. The options selected are those which are generally expected to become important in the future, as supplies of oil and natural gas become scarcer and more expensive. A companion volume will review those technologies not covered here.

Battelle, an independent research organisation, conducts research and development projects on behalf of industry and government. The institute's work spectrum ranges from investigations and studies of product and process developments to pilot plants and prototypes.

Research in the product and process development department includes investigations in the field of biotechnology. We are seeking

## a biochemist a molecular biologist a molecular geneticist

to broaden our scope in genetic engeneering.

## Qualifications:

The ideal candidate will have a post graduate qualification and experience in the area of recombinant DNA research.

The tasks will include the acquisition, execution/management of research projects, including the presentation of results. Creativity in the development of project concepts and willingness to work in interdisciplinary teams are essential advantages.

**Application:** 

Candidates should call us (0611/79082686 or 79082478) or send us their brief application. They will receive our answer by return.

Battelle-Institut e.V., Postfach 900160, Am Römerhof 35, 6000 Frankfurt am Main 90

## Chief, Invertebrate & Marine Plants Division

Salary: \$37,703 - \$47,448 (under review)

Ref. No.: 81-PSCH-DFO-12

Department of Fisheries & Oceans Halifax, Nova Scotia

Plans, directs and manages the Invertebrates and Marine Plants Division; organizes and administers activities aimed at maintaining the welfare of marine invertebrates and plant resources and maximizing continuing biological production from stocks; co-ordinates work of the Division with that of industry, provincial departments and other units within the Fisheries organization.

### Qualifications

Either graduation with an acceptable doctoral degree from a recognized university in Biology or an equivalency. (Equivalency refers to graduation with an acceptable Master's Degree or an acceptable Bachelor's Degree from a recognized university in Marine Biology coupled with acceptable research training and experience in which the capability has been clearly demonstrated to do independent research equivalent to that required for a doctoral degree.): evidence of authorship of published or unpublished reports or papers resulting from research in the field of fisheries; and recognition by the scientific community of achievement in fisheries research; experience in carrying out research projects related to marine invertebrates and plant resources and in the management of research resources, including supervision and financial budgeting and control.

Knowledge of the English language is essential.

Clearance No.: 331-259-001

Additional job information is available by writing to the address below:

Toute information relative à ce concours est disponible en français et peut être obtenue en écrivant à l'adresse

### How to apply

Send your application form and/or résumé to: Mrs. B.J. Firth, Staffing Officer Public Service Commission of Canada 4th Floor Royal Bank Building 5161 George Street Halifax, N.S. B3J 1M8 902-426-5878 Closing date, December 31, 1981

Please quote the applicable reference number at all times

## **UNIVERSITY OF MIAMI** MARINE SCIENCE

The University of Miami is searching for a Dean who will serve as the Director of its oceanographic and atmospheric Institution which has 86 full-time faculty, 162 graduate and 305 undergraduate students, and a \$14 million budget. The main function of this position is to provide leadership to a thriving, multidisciplinary community of oceanographic researchers and students, including biological, chemical, physical and geological oceanographers, ocean engineers, atmospheric scientists and specialists in marine affairs. The person who directs this Institution will be expected to promote its aims and provide liaison with federal agencies as well as private foundations, and to encourage new programs to meet the needs of both developed and developing nations, especially those of the Caribbean and South America

Applications, including a current professional résumé, nominations and further information should be sent of Dr. Norman G. Einspruch, Chairman of the RSMAS Dean Search Committee, University of Miami, School of Engineering and Architecture, PO Box 248294, Coral Gables, Florida 33124. Nominations and applications desired by December 15, 1981. Position will remain open until filled.

An Equal Opportunity/Affirmative Action Employer. (NW013)A

## **Executive Director**

## **HUNTSMAN MARINE LABORATORY** St. Andrews, New Brunswick

Applications are invited for the above position.

Founded in 1970, the HML is operated by a consortium of universities, government departments and private sector agencies at a base for research and teaching in the marine sciences. The HML also undertakes contract research in several areas of marine

Salary and starting date negotiable, but hopefully the post will be occupied by July 1, 1982. Canadian immigration regulations require that only Canadians or landed immigrants need apply for

Applicants should submit a curriculum vitae and two letters of reference to Dr W.C. Leggett, President, Huntsman Marine Laboratory, St. Andrews, N.B. E0G 2X0. Deadline for receipt of documents January 1, 1982. INWOS21A **Department of Chemistry** 

# POSTDOCTORAL RESEARCH POSITIONS

Applications are invited from well qualified candidates for one or two year appointments as Postdoctoral Research Fellows in the following fields:

Analytical chemistry; Atmospheric photochemistry; Bioinorganic chemistry; Catalysis using transition metal complexes; Chemistry atomic and solid state physics studies with Muon Spin Rotation (SR) at TRIUMF: Circular polarization in protein fluorescence; Collision theory of non-sperical molecules; Development of new synthetic methods in organic chemistry; Electron energy loss spectroscopy and coincidence experiments; Electron paramagnetic, ENDOR, Ferrocene derivatives, NQR, Mössbauer, microwave and electronic spectroscopies; Flash photolysis and kinetic spectroscopy; Fluorocarbon chemistry; Fourier transform ion cyclotron resonance spectroscopy; Homogeneous and heterogeneous catalysis; Immunochemistry of polysaccharides; Inorganic fluorine chemistry and studies in highly acidic media; Kinetic theory of gases applied to astronomy and space science; Laser bleaching studies: Magnetic resonance studies of ordered fluids including liquid crystals and biomembranes; Marine natural products; Mechanism of the intercalation of layered structures; Muonium chemistry; Non-linear optical effects in organic solids at low temperature; Nuclear magnetic resonance studies of molecular motion and of chemical shifts in solids; Organic and organometallic ion-molecule chemistry; Organic solid state reactions; Oxidation, use of coenzyme models, general acid catalysis; Phosphazene and thiazyl chemistry; Photoelectron spectroscopy including LEED. Auger and ESCA studies; Physical biochemistry of cell surfaces; Physical chemistry of biological morphogenesis; Physical chemistry of proteins; Quantum chemistry and molecular physics; Radiation chemistry and solvated electron studies; Sub-Doppler laser electronic spectroscopy: Synthesis of natural products; Synthesis of potential antiviral and antitumor compounds; Synthesis and study of organic metals; Theory of molecular relaxation and transport properties; Whole cell NMR studies; X-ray diffraction

The minimum stipend for the first year will be \$14,000. A substantial number of Teaching Postdoctoral Fellowships, with a minimum stipend of \$17,245 are open to applicants who have recently graduated and have shown superior ability in research and scholarship.

Send curriculum vitae, transcripts, and letters from three referees to the undersigned, from whom further particulars may be obtained.

J. Trotter,
Professor and Acting Head,
Department of Chemistry,
2036 Main Hall,
UNIVERSITY OF BRITISH COLUMBIA
Vancouver, British Columbia,
CANADA V6T 1Y6

(NW046)A

## THE UNIVERSITY OF MELBOURNE CHAIR OF GENETICS

The Chair of Genetics is vacant following the resignation of Professor M J Whitten.

Applications are invited from distinguished geneticists, preferably interested in eukaryotic genetics.

Salary at present is \$A41,509 per

Further information about the position, including details of application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment, is available from the Registrar of the University or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square London WC1H 0PF. All correspondence (marked "Confidential") should be addressed to the Registrar, The University of Melbourne, Parkville, Victoria 3052, Australia.

Applications close 1 Feburary 1982. (9879)A

## UNIVERSITY OF NOTTINGHAM

Medical School

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

Applications are invited from those qualified in medicine, physiology, pharmacology or cognate disciplines for a

### LECTURESHIP

which arises from the appointment of Dr C A Marsden to a Wellcome Trust Senior Lectureship within the department.

Physiology and pharmacology are taught as basic medical sciences as part of an integrated curriculum for Part I of the Bachelor of Medical Sciences degree. An Honours option in Physiology and Pharmacology is available to medical students for Part II of the degree.

There are excellent facilities for research in human and other branches of physiology and pharmacology. The current research interests of the department include carciovascular and respiratory control mechanisms; effects of exercise and training on the cardiovascular system and on skeletal muscle; the measurement of daily physical activity; control of skeletal muscle including tremor and fatigue; central neurotransmitters; the measurement of drug effects and of drug metabolism; effects of hypoglycaemia.

Salary will be within the nonclinical scale for lecturers with membership of USS. The successful applicant will be expected to take up the appointment as soon as possible.

Those interested in this post are invited to write for details and a form of application to the Deputy Registrar, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, to whom completed applications should be returned by the 11th December, 1981. (9867)A

### GEOPHYSICAL FLUID DYNAMICIST/PHYSICAL OCEANOGRAPHER

Applications are solicited for a junior faculty position in ocean physics or dynamics to begin in the academic year 1982-83. Areas of interest to the Department include analytical, numerical and laboratory modeling of physical processes and phenomena in the sea.

Yale University is an equal opportunity/affirmative action employer and encourages women and members of minority groups to compete for this position.

Curriculum vitae, publications, and the names of three or more referees should be sent by 31 December 1981 to: Robert B Gordon, Chairman, Department of Geology and Geophysics, PO Box 6666, New Haven, CT06511. (NW1009)A

## ROYAL POSTGRADUATE MEDICAL SCHOOL

(University of London)

DEPARTMENT OF MEDICINE

Immunological Medicine Unit

Applications are invited for the post of RESEARCH FELLOW

(Senior Registrar Grade) in Immunological Medicine

This post is for a medical graduate at or approaching the senior registrar (salary on the scale £9,330 -£11,900 plus £527 London Allowance), although consideration will be given to clinicians at the registrar grade or to non-clinical scientists. The appointment, which is funded by the Medical Research Council, is for the period I April 1982 31 July 1984. The successful applicant will join a multidisciplinary team under the direction of Dr M B Pepys working on the acute phase plasma protein response to tissue injury and on amyloidosis. He/she will participate in a variety of projects including biochemistry, immunochemistry and clinical measurement of acute phase and amyloid proteins in the circulation and the tissues, and clinical and pathology experimental inflammatory lesions in relation to the acute phase response and amyloidosis. The work performed will be suitable for a higher degree (MD, PhD).

Further information available from Dr Pepys, Immunological Medicine Unit, Department of Medicine, Royal Postgraduate Medical School, Du Cane Road London W12 0HS, Tel: 01-740 8970/01-743 2030 ext 258.

Application forms may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 OHS quoting reference number 2/MBP. (9876)A

# Health Physics and Safety Officer

The Northern Division of the United Kingdom Atomic Energy Authority invites applications for the above position in a team with responsibility for the Authority's Risley and Culcheth sites.

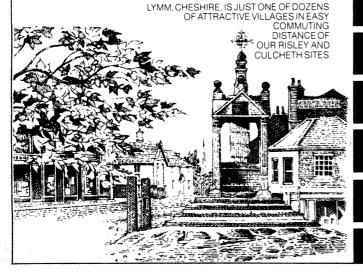

## THE WORK

The successful applicant will be responsible to the Head of the Health Physics and Safety Department for providing a complete personnel and environmental monitoring service with the support of a professional and technical team.

Duties will include assessing radiological and toxic hazards; framing operational instructions sufficient for the detailed observance of safe working practices; providing and operating a health physics advisory monitoring and emergency service; investigating radiological safety problems; advising and assisting in training programmes; representing the Department at appropriate internal and external health physics liaison meetings, and ensuring that statutory and mandatory records required for radiological protection are maintained.

## WHAT YOU NEED

Applicants should possess a relevant degree or corporate membership of an appropriate professional institution. Practical experience in the field of health physics would be an advantage.

## THE REWARDS

The position, as Professional and Technology Officer Grade 1, carries a salary ranging from £9,980 to £11,715 p.a. depending on qualifications and experience.

Conditions of employment and benefits are excellent, and include an attractive contributory superannuation scheme.

## THE PLACE

The Risley and Culcheth area features excellent schools, access to beautiful Cheshire countryside, first-class motorway links, easy connections with Manchester and Merseyside, and a wide variety of housing. Assistance with house purchase or single accommodation may be provided.

## **Senior Biochemical Engineer**

At Merck Sharp & Dohme Research Laboratories, you'll find one of the largest R&D budgets in the pharmaceutical field and programs that are guided by management keenly aware of the needs of contemporary scientists and engineers. And that can make a difference in your career.

We're now seeking a Biochemical Engineer to serve as Chief Project Engineer for the start-up of our new Fermentation R&D Pilot Plant - the most sophisticated facility of its kind in the industry — and scale-up of new technology. This leadership role re-

quires 5-7 years experience in operations of pilot plant or production scale fermentors. Working knowledge of computers, and familiarity with modern process measurement instrumentation essential. A PhD (or equivalent) in Chemical Engineering or related field and background in biochemical process programs, fermentation process scale-up and research computer applications are desirable.

To join our aggressive R&D staff, send résumé to Ms. Johanna Y. Zeltner, Ref. NA-2,

(NW047)A

## **FOREST ENTOMOLOGISTS AND** FOREST PATHOLOGIST

Vacancies exist in the Forestry Industry in the Republic of South Africa for the following permanent posts:

- 2 Graduate Entomologists
- 1 Technician with experience in Entomology
- 1 Graduate Pathologist

Appointment will be made on behalf of the Forestry Council by the Wattle Research Institute and appointees will be seconded to the Plant Protection Research Institute of the Department of Agriculture and

Location of the posts will be: One Entomologist and Technician with headquarters with the Wattle Research Institute, Pietermaritzburg, Natal.

One Entomologist with headquarters with the Department of Agriculture and Fisheries in Cape Town.

Pathologist with headquarters with the Plant Protection Research Institute in Pretoria, Transvaal.

Forestry experience will be a recommendation.

Duties will include monitoring of existing and potential forest insect pests and diseases on an individual and team basis under the direction of the Plant Protection Research Institute guided by the forestry Industry Technical Advisory Committee on Plant Protection.

Salary will be by negotiation.

Applications should be sumitted in the first instance to the Director, Wattle Research Institute, University of Natal, PO Box 375, Pietermaritzburg, 3200 Natal, Republic of South Africa, indicating present remuneration, and should be accompanied by curriculum vitae and the addresses of at least three referees. (9850)A

## UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

## SCIENTIFIC OFFICER/ POSTDOCTORAL WORKER

A vacancy has arisen for a graduate Scientific Officer or recently qualified postdoctoral worker to join a research group led by Professor Philip Cohen, who are studying the molecular mechanisms by which hormones regulate biosynthetic processes in mammalian cells. The person appointed should have a strong interest in instrumentation and will be responsible for the running of a protein sequencing laboratory comprising a Beckman 890C automated amino acid sequencer, high pressure liquid chromatography system and two amino acid analysers. The work is supported by a Programme Grant from the Medical Research Council, as well as by the British Diabetic Association, British Heart Foundation and Cancer Research Campaign.

Applications containing a full Curriculum Vitae, research interests and the names of three referees should be sent to the Personnel Office, University of Dundee, Dundee DD1 4HN, Scotland, UK, as soon as possible. The position can start immediately but candidates wishing to start at any time up to March 1st, 1982 will be considered. Please quote Ref. EST/59/81J.

UNIVERSITY OF **ALBERTA** Edmonton, Alberta, Canada T6G 2E3 DEPARTMENT OF GEOLOGY

The Geology Department has one permanent faculty position available July 1, 1982. We invite applications from qualified individuals for appointment at the

**ASSISTANT** 

or

## ASSOCIATE PROFESSOR LEVEL

in any of these areas: Geomorphology, Mathematical Geology, Engineering Geology, Process Sedimentology and Structural Geology. Preference will be given to those applicants who demonstrate an ability to pursue a vigorous research program applying modern concepts and techniques in solving geological problems. The candidate is expected to teach an undergraduate course in quantitative geomorphology, course(s) in his or her speciality, including if qualified, geostatistics. The position also involves super-vising Masters and PhD students. A PhD is required and salary is commensurate with education and ex-perience. Canadian citizens and permanent residents will be given preference.

Interested applicants should submit a résumé, publications and names and addresses of three referees to Dr NW Rutter, Chairman, Department of Geology, University of Alberta, Edmonton, Alberta, Canada T6G 2E3. Closing date for applications is February 15, 1982. applications is February 15, 1982. (NW063)A

## **UNIVERSITY OF** SUSSEX

Medical Research Council Cell Mutation Unit

## BIOCHEMIST **MOLECULAR BIOLOGIST**

Applications are invited for a Short-Term Non-Clinical post in this MRC Unit tenable for 3 to 5 years according to age and experience of the successful candidate. Candidates of immediately post-doctoral or equivalent status will be preferred, but well qualified candidates with less than 3 years postgraduate experience will also be considered

The successful candidate will work in a team studying the mechanisms of DNA repair in human cells. Some enzymological experience is desirable and the work will involve the application of recombinant DNA nology to human DNA repair genes.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information and an application form may be obtained from Dr A R Lehmann (tel: 0273 606755, ext 236). Application forms plus a full cv and the names of two professional referees should be sent to Mrs M Bunn, MRC Cell Mutation Unit, University of Sussex, Falmer, Brighton BN1 9QG by January 31st (9870)A

## UNIVERSITY OF THE WEST INDIES — JAMAICA

Applications are invited for the following posts in the faculty of National Sciences:-

## LECTURER/ ASSISTANT LECTURER IN CHEMISTRY

Applicants with special interests in Applied Chemistry or Food Chem-istry will be given preference. The appointee will be expected to play a major role in the teaching and organisation of courses in one or more of the above fields and to assist in other areas of chemistry. Contributions to the research programme in whe Department will also be expected.

## LECTURER/ ASSISTANT LECTURER IN MATHEMATICS

(2 posts)

One post should be filled by a person with teaching and research experimence in Mathematical Statistics.

Salary scales: Lecturer 1\$15,090 J\$20,049 pa; Assistant Lecturer J\$13,308 — J\$14,088 pa (£1 sterling = J\$3.30). FSSU Study and Travel Grant. Unfurnished accommodation or housing allowance.

Detailed applications (2 copies), including curriculum vitae and naming 3 referees, should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Applicants resident in the UK should also send 1 copy to the Committee for Inter-national Cooperation in Higher The British Council Education, Higher Education Division, 90/91 Tottenham Court Road, London W1P 0DT. Further details are available from either address

(9865)A

### **UNIVERSITY OF** ARERDEEN

**DEPARTMENT OF** CHEMICAL PATHOLOGY

## POST-DOCTORAL **RESEARCH FELLOW**

(supported by The British Heart Foundation)

## (Re-advertisement)

Applications are invited for the above post, tenable for a maximum of three years, from protein biochemists to work on the structure of fibrin and fibrinogen in human atherosclerotic plaques, one aspect of a long-term research programme on atherosclerosis for which the Research Fellow will take major responsibility. Experience in modern methods of protein separation essential.

Salary on Range 1A Scale, starting point up to a maximum of £6,985 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen with whom application (2 copies) should be lodged by 4 December (9869)A

## SANDOZ RESEARCH INSTITUTE in Vienna, Austria

is one of three international research centres of the Swiss based pharmaceutical company SANDOZ. We have an opening for a young

## ORGANIC CHEMIST

who by preference should have experience in the chemistry of protecting groups and in handling labile substances. This scientist will work in the field of chemical synthesis of DNA and will have his own laboratory. He is expected to have particular interests in problems of molecular biology and genetics.

The successful candidate will find excellent working conditions in well equipped laboratories. In addition, the fostering of professional contacts, and participation in specialized training courses are actively encouraged. We offer a competitive salary and all fringe benefits associated with a leading international pharmaceutical company.

Removal expenses incurred by the successful candidate will be defrayed by the Institute.

Please send curriculum vitae, list of publications and the name of referees to

Dr N. Zacherl, Personnel Manager, SANDOZ FORSCHUNGSINSTITUT, **Brunner Strasse 59** A-1235 Vienna, Austria

## UNIVERSITY OF STOCKHOLM

DEPARTMENT OF ZOOLOGY

## ETHOLOGIST OR ECOLOGIST

Applications are invited for a position as "eo docent" (roughly equivalent to US assistant professor). The position is primarily intended for a person with several years of post-doctoral research experience.

The position is advertised for a period of three years, but is usually renewed for another three year period. Starting salary L 18 (Swedish crowns 107,088 per annum = roughly 19,000 US\$).

The position is a research and teaching position, and requires a minimum of 75 hours of lecturing per annum or equivalent supervision of graduate student research, some administrative duties, and a vigorous research programme. Applicants are selected primarily on the basis of their scientific publications, but teaching experience is also required.

For further information contact: Professor T Radesater, Department of Zoology, University of Stockholm, PO Box 6801, S-113 86 Stockholm, Sweden (Telephone 00946-8340860 ext 322).

Applications including curriculum vitae plus one copy of published, accepted papers, a short summary of the applicants research and teaching experience, names and addresses of three referees and any other papers the applicant wishes to submit should be addressed to The Board of Stockholm University, Fedrik Bloms Hus, University of Stockholm, Sweden, and received no later than March 1, 1982. Quote reference number 728/81.

(W492)A

## FACULTY POSITIONS IN PATHOLOGY

The Uniformed Services University School of Medicine invites applications for tenured or tenure track faculty appointments in the Department of Pathology at the levels of Professor, Associate Professor, or Associate Professor. Levels of appointment and salaries will be commensurate with training and experience. Candidates should have MD, PhD or related professional degrees, appropriate postdoctoral training or experience, teaching abilities, and demonstrated excellence in research.

Interested candidates should submit curriculum vitae, bibliography, and names of three professional referees by 30 November 1981 to Dr Robert Friedman, Chairman, Department of Pathology, c/o Personnel/Manpower Division, Uniformed Services University of the Health Sciences, 4301 Jones Bridge Road, Bethesda, MD 20014. The Uniformed Services University is an equal opportunity/affirmative action employer. (NW061)A

### PLANT ECOLOGIST University of California Davis

Applications are invited for a tenuretrack faculty position at the assistant professor and assistant botanist levels, available 1 July 1982. The individual selected will be expected to develop a vigorous research program in plant population and community ecology, to teach undergraduate and graduate courses in botany and plant ecology, and develop a strong graduate training program. The appointment is split between the College of Letters and Science (.6) and the Agricultural Experiment Station (.4) and has a salary commensurate with the assistant professor range (11-month appointment) at the University of California. Send applications with curriculum vitae, statements of research and teaching interests (including long-term goals), transcripts, and request that 3 letters of recommendation be sent to: Dr. R. W. Pearcy, Chairperson of the Search Committee, Department of Botany, University of California, Davis, CA 95616. Applications must be postmarked by 1 January 1982. The University of California is an Affirmative Action/Equal Opport-unity Employer. (NW067)A unity Employer.

## BROWN UNIVERSITY

## POSTDOCTORAL RESEARCH ASSOCIATE

To work on on an experimental study of the infrared spectroscopy of van der Waals molecules of atmospheric significance. A recent Ph.D. in physical chemistry preferred with experimental experience in one or more of the following: molecular beams, IR spectroscopy, diode lasers, apparatus/computer interfacing.

Send résumé and names of three referees by 1 December to: Professor J.M. Calo, Division of Engineering, Box D, Brown University, Providence, Rhode Island 02912. An Equal Opportunity/Affirmative Action Employer. (NW058)A

## **ENTOMOLOGIST**

Assistant Professor, 12-month, tenure-track position for insect ecologist with background in medical/veterinary entomology to conduct research on biting flies affecting man and animals in New Jersey and to teach undergraduate and graduate courses in medical/veterinary entomology and insect ecology, or in his/her specific interest area. Position is budgeted as two-thirds research, one-third teaching.

Send application, including résumé, transcripts, and three letters of reference, to: Dr H.T. Streu, Department of Entomology and Economic Zoology, Rutgers — The State University of New Jersey, New Brunswick, N.J. 08903.

(NW059)A

## Molecular Genetics of Yeast

A yeast or microbial Geneticist is required to join a group involved in the genetic modification of brewing yeasts. The person appointed will work for the UK's largest brewing group in the Research Department, located in Burton-on-Trent, Staffordshire.

The successful applicant will contribute to the development of genetic systems for brewing yeasts, including recombinant DNA techniques and their application to achieve technical and commercial objectives. He/she will possess a Ph.D. in a relevant field of genetics or molecular biology and have made extensive use of genetic techniques during their research, possibly with some post-doctoral experience. Practical experience with protoplast fusion and/or cloning is desirable, but not essential.

Applicants should be innovative and possess the initiative to progress towards defined objectives. The person appointed will be encouraged to maintain and extend liaison with academic laboratories and to publish results where appropriate.

Salary will be commensurate with age and experience. The Company operates a generous life assurance and pension scheme and provides comprehensive recreational facilities.

Detailed applications, including a curriculum vitae and the names of two referees, should be sent as soon as possible to:-

Recruitment and Training Manager, Bass Brewing Limited, Burton-on-Trent, Staffordshire, DE14 1JZ.

## Bass Limited

(9883)A

### UNIVERSITY OF HEIDELBERG Germany

## **Graduate Research Assistant**

Applications are invited from graduates having or expecting to obtain a 1st or upper 2nd class degree.

The successful applicant will work on mechanisms of gene expression (structure-function relationship of procaryotic promoters, terminators, rib. binding sites).

Methods to be used will include: chemical and biochemical manipulation of DNA signal sequences, cloning in plasmids, DNA sequencing, quantitation of gene products in vivo and in vitro.

The salary will be between 1,800 and 2,000 DM per month.

Applications (including curriculum vitae and the names and addresses of two referees) should be sent to Prof. Dr Hermann Bujard, Institut für Molekulare Genetik, Universität Heidelberg, Im Neuenheimer Feld 230,6900Heidelberg, FRG. (W487)A

## THE DEPARTMENT OF PHYSIOLOGY & BIOPHYSICS is seeking candidates for two new FACULTY POSITIONS

Applicants must have a doctoral degree and several years of postdoctoral experience, and should be prepared to carry out independent research & to participate in the teaching activities of the department. We will consider applicants in any area of physiology or biophysics, but will give preference to people working in the area of cellular neurobiology, membrane physiology & theiregulation of metabolism.

We plan to appoint tenure-tract associate & assistant professors, but will also consider applicants for appointment as tenured asseciate and full professors.

Applicants should send their curriculum vitae and bibliography. Reprints of several recent papers a statement of current research interest, and the names of three references to: Dr Robert L Perlman, Head, Department of Physiology & Biophysics, University of Illinois College of Medicine, PO Box 6998 Chicago, IL 60680.

(NW973)A

## **PSYCHOPHYSICIST**

Unilever Research, Port Sunlight, wishes to recruit a Scientist experienced in recent developments in psychophysical theory and methodology

For this post we are looking for a Scientist having a First Degree in Psychology followed by either:

- (a) a Ph.D in Psychophysics or
- (b) a Ph.D in a relevant subject such as physical or biological science or experimental psychology,

plus in either case at least three years of post-doctoral research in psychophysics.

The Company operates a progressive salary and promotion policy, good superannuation and life cover benefits and where appropriate, will assist with removal expenses, legal fees, etc.

The Laboratory is conveniently situated for access to Liverpool, Chester and North Wales.

Please write for an Application Form Quoting Ref: PS 733 M to:

> **Personnel Officer Recruitment & Placement Unilever Research Port Sunlight Laboratory** Quarry Road East, Port Sunlight, Wirral Merseyside.

## **UNIVERSITY OF ZIMBABWE**

Applications are invited for the following posts

Academic

## LECTURESHIP/SENIOR LECTURESHIP IN THE **DEPARTMENT OF GEOLOGY** (available 1 April 1982)

Applicants must have a sound knowledge of metamorphic and structural geology. Minimum qualification is a PhD and practical field experience is essential.

Research Fellowships

## **FACULTY OF SCIENCE (2 posts)** (available 1 January 1982)

Applicants should have a PhD degree in one of the following disciplines: biochemistry, Botany, Computing Science, Chemistry, Geology, Mathematics, Physics or Zoology.

Salary Scales (approx. Stg. equivs.)

Academic Staff

Lecturer Grade II:

Lecturer Grade I:

 $\begin{array}{l} £\ 5,291\times380-£7,191+398-£9,181\\ £\ 9,604\times398-£11,196\\ £10,600\times398-£11,794\times408-£13,835 \end{array}$ Senior Lecturer:

Research Fellows

Junior Research Fellow: £4,013 × 263 - £4,802 Research Fellow Grade II: £5,064 × 344 - £6,440 £7,483 × 389 — £9,042 £8,516 × 389 — £11,243 Research Fellow Grade I: Senior Research Fellow:

Further particulars on the above posts, on conditions of service and on method of application should be obtained prior to submitting an application from Director, Appointments & Personnel, University of Zimbabwe, PO Box MP. 167, Mount Pleasant, Salisbury, Zimbabwe or from the Association of Commonwealth Universities (Apps), 36 Gordon Square, London WC1H 0PF.

Applications should be submitted by 30 November 1981 for Academic posts and 20 November 1981 for Research Fellow posts, or as soon as (9871)A possible thereafter.

### POSTDOCTORAL POSITION

available for Cell Biologist with strong background in biochemistry to investigate the structure and function of organelles involved in cell wall formation by plant cells and protoplasts. Some knowledge of plant tissue culture and/or electron microscopy is desirable. The position is available immediately for a one year term (renewable for a second year) at a salary of \$15,000.00 to \$18,000.00 depending on experience and qualifications. Some travel assistance is available.

Interested candidates should send curriculum vitae and 2 letters of recommendation to Dr L C Fowke, Department of Biology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0WO.

(NW026)A

## **BIOTECHNOLOGY** RESEARCH

Applications are invited from

## **BIOCHEMISTS** or **MICROBIAL PHYSIOLOGISTS**

to join a group studying microbial biotransformations. Ideally, candidates will have some post-doctoral experience and will have worked on microbial biotransformations catalysed by oxygenases. The research is industrially funded.

Salary will depend on qualifications and experience and will be within the range £6,070 to £7,700 per annum. Initially, the appointment will be for a period of two years.

For an application form and further information contact: Personnel Section, Cranfield Institute of Technology, Cranfield, Bedford MK43 OAL. Tel Bedford (0234) 750111, ext 477. (9889)A

## UNIVERSITY OF WINNIPEG

DEPARTMENT OF BIOLOGY MICROBIOLOGY

Applications are invited for a

TENEURE STREAM POSITION AT THE RANK OF ASSISTANT, ASSOCIATE OR FULL **PROFESSOR** 

Candidates should have a PhD and relevant experience in teaching and research

Teaching duties will include a course in general microbiology plus other duties as required.

Salary dependent on qualifications and experience.

Applications together with the names of three references should be sent to: Dr R A Woods, Chairman, Department of Biology, University of Winnipeg, Winnipeg, Manitoba R3B 2E9.

Closing date: when position is filled. Starting date: not later than August 1st, 1982. Only Canadians or permanent residents need apply for this position. (NW068)A this position.

## UNIVERSITY OF THE WITWATERSRAND Johannesburg, South Africa DEPARTMENT OF CHEMISTRY POLYMER RESEARCH **PROGRAMME** SENIOR RESEARCH OFFICERS/RESEARCH **OFFICERS**

Applications are invited from suitably qualified persons, regardless of sex, race, colour or national origin for appointment to the above posts. Work on challenging and unconventional aspects of organic and organometallic (including macromolecular) chemistry is being done. Applicants should have a liking for demanding (notably synthetic) experimentation, although no previous specialized experience is required. Appointees to pre-doctoral post may apply to work for a higher degree on a part-time basis. Only highly motivated applicants with good academic records will be considered. Appointments will be for one to three years in the first instance (with the possibility of renewal).

Intending applicants should obtain the information sheet relating to this post from the Secretary, South African Universities Office, Chichester House, 278 High Holborn, London WCIV 7HE. Tel: 01-405 5834, or from the Director: Personnel Office, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, 2001, with whom applications should be lodged not later than 30 November,

## UCLA SCHOOL OF **MEDICINE**

DEPARTMENT OF MICROBIOLOGY AND **IMMUNOLOGY** 

## **FACULTY POSITION**

Academic appointment for tenure track Assistant Professor with training in the area of macrophages as they relate to pathogenesis of diseases. Applicant must possess postdoctoral experience in the general fields of Biology, Microbiology and/or Immunology. Applicant must be able to develop an independent research program and interact with members of Department with emphasis in Microbiology, Immunology and Virology. Responsibilities include participation in the Departmental teaching of Medical, Dental and/or Graduate students, as well as development of a graduate course in the field of interest.

Applicants should submit curriculum vitae, list of publications, a brief description of current and future interests, and names of at least three referees. Deadline for receipt of applications: January 31, 1982. Send applications to: Ben Bonavida, Associate Professor or Jack Stevens Professor & Chairman, Dept of Microbiology and Immunology, UCLA School of Medicine, University of California at Los Angeles, Los Angeles, CA 90024. UCLA is an equal oportunity and affirmative (NW060)A action employer.

## UNIVERSITY OF WESTERN **AUSTRALIA** Perth **POSTDOCTORAL** RESEARCH ASSOCIATE IN GEOCHRONOLOGY

Applications are called for appointment to the above-mentioned position n the Department of Geology for a period of two years commencing early n 1982. The appointee will work with Ors M J Bickle, D I Groves and J R de Leater on an ARGC Funded project on the evolution of early Archaean crust of the Shaw Batholith, Pilbara Block, Western Australia.

The project is part of an on-going ield-based study of the structural hermal and chemical evolution of the early Archaean crustal segment exposed in the Shaw Batholith, a particularly well exposed area, showing a transitional character etween a gneiss terrain and a granitoid-greenstone terrain. The aim of the project is to date the tectonic volution of the area using Rb-Sr, Pb-Pb, U-Pb in zircon and Sm-Nd sechniques. The applicant should have expertise in solid source mass spectrosopy and clean laboratory chemistry Experience of U-Pb in zircon methods would be an advantage.

Salary range: \$A17,083 — \*A19,570 per annum. Some assistance will be provided towards relocation expenses.

Further information can be obained from either Associate Professor I Groves, Department of Geology, Jniversity of Western Australia, Nedands, Western Australia, 6009, or Dr

J Bickle, Department of Mineraland Petrology, University of Cambridge, Downing Place, Cam-wridge CB2 1TN.

Applications in duplicate stating ull personal particulars, qualifica-ions, experience and the names and ddresses of two referees should reach he Staffing Officer, University of Western Australia, Nedlands, Vestern Australia 6009, by 23 December 1981. (9878)A

## RESEARCH ASSOCIATE **AND** POSTDOCTORAL FELLOW

Positions immediately available to study biochemical and cell biological aspects of cholinergic excitation as part of an active research group devoted to this area. Previous experience in tissue culture, membrane biochemistry or in work with monoclonal antibodies would be advantageous.

Send curriculum vitae and the pames of two referees to Dr A Maelicke, Max-Planck-Institute, Rheinlanddamm 201, D-4600 Dortmund, West Germany. (W488)A

## X-RAY **SPECTROSCOPIST**

## for Geochemical Exploration Johannesburg - South Africa

In the Anglo American Research Laboratories a vacancy exists for an X-ray Spectroscopist/Geochemist preferably with experience in computer programming. Recent graduates will be favourably considered. The laboratories. situated in Johannesburg, function in a service, research and development capacity for the Anglo American Corporation. Although involved in a diversity of operations, the Corporation is principally a mining concern. Prospecting on an extensive scale is a vital function and X-ray fluorescence is one of the more important techniques employed for the determination of a large variety of elements in the prospection samples.

The most sophisticated equipment is used, including two multi-channel units with automatic sample changers. One of these units incorporates both wavelength and energy dispersive spectrometers, enabling automated simultaneous determination of many elements with high sample throughout. Computer programs are used for both on and off line data manipulation, tabulation, statistical evaluation, interpretation and contour mapping of analytical results. In certain aspects of the work the XRF laboratory is considered to be a world leader. Research and development of new methods and expansion of programs are on-going operations, for which well qualified personnel are required.

Employment benefits include a guaranteed 10% annual bonus, housing loan, furniture loan scheme, settling in and removal allowance and provision of temporary accommodation, free luncheons, pension and medical aid scheme and group life insurance.

Please write with full personal and career details, quoting reference SN 81/81, to: Ms. Sandy Cook, Anglo Charter International Services Ltd., (Appointments Division), 40 Holborn Viaduct, London, EC1P 1AJ

## ABOUT SOUTH AFRICA

Our climate lends itself to outdoor life and all sporting facilities are readily available. Our income tax rates are lower, VAT is only 4 per cent and the cost of living is lower than in the UK. Our schooling is of a high standard and we pride ourselves on the calibre of our medical facilities

South Africa has many attractions - we hope that you will want to share these with us.

## **University of Utrecht**

The Subfaculty of Physics and Astronomy of the Rijksuniversiteit Utrecht invites applications for the position of

## **Professor of Biophysics**

in the Biophysics Department. The candidates should have broad experience in the applications of physical techniques to structural studies of biological systems and will be expected to participate in the research activities of the department. The research programme includes optical spectroscopy, electron spin resonance, pulse radiolysis and dielectric studies of the dynamic structure of plant and model membranes. Duties also include teaching at undergraduate and graduate level within the Subfaculty. Candidates should be willing to serve on subfaculty boards and committees. Further details can be obtained from Professor Y.K. Levine, Biophysics Department, Fysisch Laboratorium, Rijksunversiteit Utrecht, P.O. Box 80.000, 3508 TA Utrecht, The Netherlands, tel. (030) 532363/631653.

Gross salary, depending on age and experience, ranges from Dfl.6352 to Dfl.9075 per month.

Applications, including a curriculum vitae, should be sent to the Chairman of the Selection Committee, Professor H.W. de Wijn, Fysisch Laboratorium, Rijksuniversiteit Utrecht, P.O. Box 80.000, 3508 TA Utrecht, The Netherlands, before 15 January 1982, under no. IL/2.013. Suggestions of suitable candidates will also be appreciated. Candidates should be willing to learn Dutch within two years.

(W489)A

## UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH WELSH PLANT BREEDING STATION

Aplications are invited for the post of

## SCIENTIFIC OFFICER (I) HIGHER SCIENTIFIC OFFICER (I)

in the Station's Grassland Agronomy Department. This is a new post created under the Welsh Hills and Uplands R&D programme. The successful candidate will join the Department's exiting Hills and Uplands team but will carry out most of the field work at Pwllpeiran Experimental Husbandry Farm.

Candidates should possess a First or upper Second Class honours degree in agricultural, biological or soil science with at least two years relevant post graduate experience for appointment as HSO. Preference will be given to candidates with a PhD and a Knowledge of hill farming conditions.

Pay Scales: (SO) £5,176 - £6,964 (HSO) £6,530 - £8,589. Starting Salary according to qualifications and experience. Noncontributory pension scheme but male employees aged 18 or over contribute 1 ½ % to Widows and Orphans Fund.

Further particulars and application forms are available from The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed. Closing Date for applications is 27 November 1981. (Quote reference 68). LA TROBE UNIVERSITY Melbourne, Australia SCHOOL OF BIOLOGICAL SCIENCES

DEPARTMENT OF GENETICS AND HUMAN VARIATION

## LECTURER (Tenurable)

A position is available for early 1982 for a lecturer with research experience in molecular aspects of eukaryote gene structure and expression. Applicants should have a strong training in general genetics as some undergraduate teaching in prokaryote genetics will be required. The appointee will be expected to be actively involved in research, including the supervision of honours and postgraduate students.

The facilities of the Department include glasshouse, growth cabinets, constant temperature rooms, a Cl containment room, analytical and other centrifuges as well as routine items of potential assistance for a molecular geneticist.

Applicants for the previously advertised fixed-term appointment will be considered and need not reapply

Salary: \$A19,821 - \$A26,037.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications marked confidential and quoting reference number 150/32/22 close with the Staff Officer, La Trobe University, Bundoora, Victoria, Australia, 3083 by 11 December 1981. (9859)A

## THE INSTITUTE FOR ADVANCED STUDY

will have several openings for members in theoretical physics and astrophysics for the academic year 1982-83. The positions are at a post-doctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of elementary particles, mathematical physics, astro-physics, plasma physics, general relativity and statistical mechanics. Preference is given to candidates who have received their PhD within the last year or two.

Postdoctoral members frequently collaborate with each other, with faculty members at the Institute or Princeton University, and with researchers at other institutions.

Appointments ae usually for no more than two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are encouraged to apply.

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW 1006)A

## FACULTY POSITION IN SPACE PHYSICS

The Department of Physics at Utah. State University is seeking candidates for a tenure track faculty position. Preference will be given to senior applicants who are actively working in space physics, particularly in the areas of stratospheric research, atmospheric chemistry of space plasma physics. The position will involve teaching the graduate or undergraduate level, guidance of graduate students and continuing research work within the center for Atmospheric and Space Sciences. Rank and salary will be commensurate with experience.

Please send résumé, a statement of research interests and the names of three professional references by December 31, 1981 to: Dr W J Raitt, Chairperson, Search Committee, Department of Physics, UMC-41, Utah State University, Logan, Utah 84322, USA, Utah State is an Affirmative Action/Equal Opportunity Employer. (NW050)A

ASSISTANT PROFESSOR, Surface Science. Rensselaer Polytechnic Institute is seeking outstanding applicants for this tenure-track position in physical chemistry. Minorities and women are particularly encouraged to apply. The appointee will be expected to develop a vigorous research program and to teach in the chemistry department at the undergraduate and graduate levels. Curriculum vitae, list of publications, and summary of research plans should be submitted, and arrangements made for three letters of recommendation to be sent, to James P. Ferris, Chairman, Department of Chemistry, Rensselaer Polytechnic Institute, Troy, NY 12181. RPI is an Equal Opportunity/Affirmative Action Employer. (NW057)A

## NATIONAL COLLEGE OF AGRICULTURAL ENGINEERING (A School of Cranfield Institute of Technology)

## TEACHING ASSOCIATE POST

Applications are invited for a Teaching Associated post in Agricultural Science and Production to assist academic staff with their teaching and related work.

Candidates should have a good honours degree in a relevant discipline and desirably have experience of tropical and temperate agriculture. The post is tenable for two years in the first instance. Salary, within the range £5,285 — £7,700 per annum.

An application form and further particulars may be obtained from: The Head of Administration. National College of Agricultura Engineering, Silsoe, Bedford MK45 4DT. Telephone Silsoe, (0525) 60426 (9890)A

## PUBLIC HEALTH LABORATORY SERVICE BOARD

Central Public Health Laboratory — Colindale Applications are invited for

JUNIOR MEDICAL LABORATORY SCIENTIFIC OFFICERS (Grade B)

or

## STATE REGISTERED MEDICAL LABORATORY SCIENTIFIC OFFICER POSTS

Candidates applying at Junior B level should possess 'A' Levels in Chemistry and one other science subject or an appropriate Science Degree and be prepared to follow the relevant courses leading to State Registration. Training is given in all aspects of Microbiology and will include a period spent in a routine clinical microbiology laboratory outside Colindale.

Currently, vacancies exist in Divisions of Enteric Pathogens and Microbiological Reagents and Quality Control as well as within the Central Organisation.

Further information and application forms can be obtained from the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, Colindale, London NW9 5HT. Telephone 01-205 7041.

(9858)A

ASSISTANT, ASSOCIATE or Full Professor of Entomology to teach insect behaviour and conduct fundamental and/or applied research in insect behaviour with application to practical problems. PhD required. Submit curriculum vitae, transcripts, description of research experience and goals, summary of teaching experience, reprints of publications, dissertation summary, names of 3 referees to H K Kaya, Chair, Search Committee, Department of Entomology, University of California, Davis, CA 95616 by December 31, 1981. An Equal Opportunity/Affirmative Action Employer.

(NW056)A

## YALE UNIVERSITY DEPARTMENT OF GEOLOGY AND GEOPHYSICS

Applications are solicited for a faculty position in solid earth geophysics to begin in the academic year 1982-83. Areas of interest to the Department include seismology, exploration geophysics, mechanical and physical properties of rocks and minerals, geomagnetism, and tectonophysics.

Yale University is an equal opportunity/affirmative action employer and encourages women and members of minority groups to compete for this position.

Curriculum vitae, publications and the names of three or more referees should be sent by 31 December 1981 to Robert B Gordon, Chairman, Department of Geology and Geophysics, PO Box 6666, New Haven CT 06511. (NW1010)A

## HAMMERSMITH HOSPITAL

DEPARTMENT OF MEDICINE

## BASIC GRADE BIOCHEMIST

£5,988 — £8,396 pa, according to qualifications and experience. Required for Hormone Assay Laboratories in the Endocrine Unit.

The laboratories provide service radioimmunoassays for Hammersmith Hospital, the Regional Health Authority and the Supra-Regional Hormone Assay Service; and are engaged in research in most aspects of endocrinology, particularly pituitary disorders.

Science Degree required, and previous experience in this field is an advantage.

Application forms and further details available from the District Personnel Department, Hammersmith Hospital, Du Cane Rd, London W12. Tel: 01-743 2030 ext 49.

N.B. This is a readvertisement of an MLSO post: previous applicants need not apply. (9881)A

## GRAVITATIONAL WAVE DETECTION AND EXPERIMENTAL GRAVITY — LSU

A postdoctoral position is available in the gravitional radiation group at Louisiana State University. We have a cryogenic tuned bar detector which is sensitive to strains of  $10^{-17}$  at  $4.2 \, \text{K}$ . We are developing a Josephson junction parametric amplifier as part of the detection scheme. We are also investigating the applicability of various quantum-non-demolition techniques. Other investigations related to experimental gravitation may be undertaken.

Inquiries from women and members of minorities are encouraged. Contact W O Hamilton, Department of Physics and Astronomy, LSU, Baton Rouge, La. 70808. LSU is an equal opportunity employer.

(NW049)A

## UNIVERSITY OF EDINBURGH

DEPARTMENT OF MOLECULAR BIOLOGY Applications are invited for a

## POST-DOCTORAL RESEARCH

position to investigate the molecular mechanism of conjugal DNA transfer by bacterial plasmids. Experience in molecular genetics and/or in vitro DNA manipulation is desirable. The appointment is available from 1 January 1982, and will be for 2 years. Salary on Research Range 1A at a point commensurate with age and experience

Applicants should send a CV, reference and letter describing their research interests to Dr N S Willetts, Department of Molecular Biology, University of Edinburgh, King's Buildings, Edinburgh EH9 3JR. Please quote Reference 5064.

Senior Research Assistant Applications are invited for the acancy of Postdoctoral Senior Research Assistant in the Department of Biochemistry. The successful applicant will work with Professor E. G. Brown and Dr. R.P. Newton on an SRCsponsored project concerning the isolated and complex-bound cyclic nucleotide phosphodiesterases of plant tissues. Preference will be given to applicants with experience in the extraction and purification of enzymes and/or the isolation of plant organelles.

The commencing salary is on a scale up to £6,880 per annum plus USS/USDPS benefits, and the appointment is for one year in the irst instance, renewable for a urther year.

Further particulars and application forms may be obtained from the Personnel Office, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to which office they should be returned by Friday, December 11, 1981.

## RESEARCH ASSOCIATE (Postdoctoral)

DEPARTMENT OF **PHARMACOLOGY** 

This position available for studies on the control of insulin release. Emphasis on calcium handling at the subcellular level and the role of calcium in exocytosis. Both physio-logical and biochemical techniques will be used.

Applications should be sent to Dr Geoffrey W G Sharp, Chairman, Department of Pharmacology, New York State College of Veterinary Medicine, Cornell University, Ithaca, New York 14853. Cornell University is an Affirmative Action/ Equal Opportunity Employer.
(NW064)A

## HIGH ALTITUDE OBSERVATORY

Visitor Appointments at the High Altitude Observatory are available for new and established PhD's for up to one year periods to carry out research in solar physics, terrestrial physics, and related subjects. Applicants should provide a curriculum vitae including education, work experience, publications, the names of three scientists familiar with their work, and a statement of their research plans. Applications must be received by 15 January 1982, and they should be sent to: Visitor Committee, High Altitude Observatory, National Center for Atmospheric Research (NCAR), PO Box 3000, Boulder, Colorado 80307, NCAR is an Equal Opportunity/Affirmative Action Employer. (NW931)A

### THE DISTILLERS **COMPANY LIMITED ASSISTANT SCIENTIST**

The Food Group of the Distillers Company Limited require an Assistant Scientist for work in the Spirit Yeast Fermentation Laboratory of their Yeast Research Department, Menstrie, Clackmannanshire.

Applicants should have a HNC qualification in chemistry, preferably with 2 or 3 years laboratory experience in the use of fermentation or biochemical techniques and including the handling of gas liquid chromatography equipment. Applications from candidates possessing qualifications other than HNC will not be considered further. The person appointed would be directly responsible to the Microbial Biochemist in charge and would assist him in research projects as well as in routine laboratory work with eventual responsibility for day to-day laboratory operations

An application form can be obtained

by writing to: The Yeast Research Manager, The Distillers Company Limited, Food Group,

Research Department, MENSTRIE,

Clackmannanshire FK11 7ES. Closing date for applications is November 20th, 1981. (9816) A

## **LECTURES**

UNIVERSITY College London (Gower St, WC1E 6BT). The Smith, Kline & French Lecture in Allied Health Sciences by Professor K. Murray, 'Opportunities for Genetic Engineering in Biomedical Science', Tues. 17 November at 5.30 in the Botany Theatre. Admission Free. Without Ticket. (9860)K

## **AWARDS**

### **POSTDOCTORAL AWARDS IN OCEAN** SCIENCE AND **ENGINEERING**

Woods Hole Oceanographic Institution invites applications for 1-year postdoctoral scholar awards from new and recent doctorates in fields of biology, chemistry, engineering, geology, geophysics, mathematics, meteorology, and physics, as well as oceanography. Recipients of awards are selected on a competitive basis, with primary emphasis placed on research promise.

Fellowship stipend is \$20,000. Appointees are eligible for group health insurance and a modest research budget. Recipients are encouraged to pursue their own research interests independently or in association with resident staff.

Completed applications must be received by 1 February 1982 for 1982–1983 awards. Awards will be announced in March. Write for application forms to: Dean of Graduate Studies, P.O. Box N. Woods Hole Oceanographic Insti tution, Woods Hole, Massachusetts 02543.

Equal Opportunity/Affirmative Action Institution (NW053)N

### **ASSISTANTSHIPS**

## THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF VIROLOGY

### Applications are invited for a RESEARCH ASSISTANTSHIP

funded by the MRC, and tenable for three years from 1 January 1982. The appointee will work on the immunogenicity of vaccines prepared from recombinant influenza viruses.

The work involves virological, immunological and biochemical techniques, including electron microscopic studies. A good honours degree in biological/biochemical subject required.

Initial salary of £5,285 a year (Range IB for Research and Analogous Staff), and the successful applicant will register for a PhD

Applicants should send their curriculum vitae, together with the names and addresses of two academic referees to Dr R Jennings, Department of Virology, University of Sheffield Medical School, Beech Hill Road, Sheffield S10 2RX. (Tel. 0742 26484 ext 2019), by 27 November 1981. Quote ref: R645/G. (9884)P

## CONFERENCES and **COURSES**

## SCIENTIFIC **GLASSBLOWING**

Day and evening classes are held in the Science Department of Hounslow Borough College, St. John's Road, Isleworth, Middx. Tel: 01-568 0244. (9856)C

We would like to call the following announcement to the attention of your readers:

THE ERNEST WITEBSKY CENTER FOR IMMUNOLOGY State University of New York at Buffalo announces the

## EIGHTH INTERNATIONAL CONVOCATION ON IMMUNOLOGY

to be held June 14-17, 1982 at the Buffalo Marriott Inn,

Amherst, New York.

The theme of the program, "Regulation of the Immune Response' include presentation of papers by distinguished scientists internationally recognized as experts on the topics: Systematic Immuno-regulatory Mechanisms; Mucosal Immunoregulatory Mechanisms; Immune Regulation to Exogenous Antigens; and Implications in Clinical Disease States.

Further information may be obtained by contacting Dr James F Mohn, Director, The Ernest Witebsky Centre for Immunology, Room 210 Sherman Hall, State University of New York at Buffalo, Buffalo, New York 14214 USA, (telephone AC 716-831-2848).

(NW045)C

## HEAT SHOCK INDUCTION OF PROTEINS May 5-May 8, 1982

Organized by:

Michael Ashburner University of Cambridge

Milton J. Schlesinger Washington University

**Alfred Tissières** University of Geneva The conference will focus on such subjects as:

Heat Shock Genes & Their Organization.

Nucleosome Structure & Function in Heat Shock. Transcription & Translation of Heat Shock mRNAs.

Heat Shock Proteins: Structure, Localization in the Cell, Possible Functions,

Conservation of Structure among Species.

Biological Effects of Heat Shock: Protection, Role in Homeostasis.

Relation to Cell Transformation. Hyperthermia in Chemotherapy.

## IN VITRO MUTAGENESIS MEETING May 12-May 16, 1982

Organized by:

Robert Schleif Brandeis University

**David Shortle** 

State University of New York,

Stony Brook

**R. Bruce Wallace**City of Hope Hospital

The projected agenda will cover such topics as:

Directed Synthesis of Mutant Sequences.

Synthesis Using Base Analogues.

Site-directed Mutagenesis. Deletions.

DNA Repair In Vivo and Chemical Modification In Vitro.

Putting Mutagenized DNA Where You Want It.

Applications & Accomplishments.

## RNA PROCESSING May 19-May 23, 1982

Organized by:

John J. Dunn Brookhaven National Laboratory

Michael B. Mathews

Cold Spring Harbor Laboratory

Joan A. Steitz Yale University Topics to be covered will include:

Large and Small Ribonucleoprotein Particles.

Small RNAs.

RNA:RNA & RNA:Protein Interactions. tRNA, mRNA, and rRNA Processing.

mRNA Splicing.

To obtain further information and registration material for the above meetings and/or the complete summer meetings schedule, please contact:

Meetings Coordinator, Cold Spring Harbor Laboratory, Box 100, Cold Spring Harbor, New York 11724. (516) 367-8345

## **FELLOWSHIPS**

## E M B O

## **EUROPEAN MOLECULAR BIOLOGY ORGANIZATION** SHORT TERM FELLOWSHIPS in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of the application.

Applications for exchanges between laboratories within any one country cannot be considered.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, 69
Heidelberg 1, Postfach 1022.40, F.R.G. (W490)E

### **UNIVERSITY OF** BIRMINGHAM

**DEPARTMENT OF BIOCHEMISTRY** 

## RESEARCH FELLOWSHIP

Applications are invited for a Research Fellowship for three years to work with Dr N J Kuhn on an ARC sponsored project to establish and biochemically study mammary epithelial monolayers on floating collagen gels. Applicants should have suitable postgraduate experience, preferably including cell culture.

Starting salary within the range £6,070 — £6,880 pa (plus superannuation) depending on age, qualifications and experience.

Applications (2 copies) including a curriculum vitae and the names of three academic referees, should be sent by 30 November 1981, or as soon as possible thereafter to Jane Nelson, Senate Registry, University of Bir-mingham, PO Box 363, Birmingham, B15 2TT, from whom further particulars may be obtained. (9868)E

### THE WEIZMANN **INSTITUTE OF SCIENCE** Rehovot, Israel

Offers Postdoctoral Fellowships in the life sciences (biology, bio-chemistry, biophysics), chemistry (physical, organic, geological and biological), mathematical sciences, physics and science teaching. The fellowship provides a 12-month

stipend (which is adjusted to the costof-living index), a relocation allowance and one-way air-fare. Fellowships which are renewed for a second year provide round-trip airfare.

Application forms and additional in-formation may be obtained from the Feinberg Graduate School, of the Weizmann Institute of Science Rehovot 76-100, Israel.

The applications should reach the above address not later than May 15, 1982, for fellowships starting in September 1982 and not later than November 15, 1982, for fellowships starting in April 1983. (W496)E

### IMPERIAL CANCER RESEARCH FUND

**DEVELOPMENTAL GENETICS** LABORATORY (MILL HILL)

## **POSTDOCTORAL** RESEARCH FELLOWSHIP

Applications are invited for a three year postdoctoral appointment, starting September 1982, to work on the molecular genetics of pattern for-mation in *Drosophila*. The project involves the study of genes affecting the establishment of early embryonic pattern. The work makes use of recombinant DNA technology, genetic analysis and embryology, and experience of one of these techniques would be useful although not essential.

Salary range £7,700 to £9,750 plus Outer London Weighting (rate under review) with entry according to qualifications and length of post-doctoral experience.

For further information contact Dr D Ish-Horowicz at ICRF, Burtonhole Lane, Mill Hill, London NW7. Applications supported by full type-script CV, including date PhD ob-tained, list of publications and names and adresses of two referees, should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 by 31st December 1981 quoting reference 7/82. (9854)E 7/82.

## **STUDENTSHIPS**

## HANNAH RESEARCH INSTITUTE

University of Glasgow Applications are invited for a PhD STUDENTSHIP

tenable at the Biochemistry Department and funded by the UKDA Nutritional Consultative Panel, to work on the dietary regulation of hepatic and intestinal cholesterol metabolism.

Applicants must hold or expect to obtain a First or Second Class (Upper) degree in Biochemistry or closely related discipline and should send their cv and names of 2 academic referees to: The Secretary, Hannah Research Institute, Ayr KA6 5HL, (9875)F Scotland.

## THE ROYAL SOCIETY **BROWNE RESEARCH FUND**

**MAURICE HILL** RESEARCH FUND MARSHALL AND **ORR BEQUEST** 

## **GRANTS AND RESEARCH FELLOWSHIPS 1982**

The Council of the Royal Society invites applications from qualified research workers for personal grants:

(a) from the Browne Research Fund, for research in marine biology at a marine biological laboratory or elsewhere. Preference will be given to those who propose to work on purely scientific problems rather than to those whose work would be primarily directed towards an economic end.

(b) from the Maurice Hill Research Fund (established in memory of the late Dr M N Hill, FRS) for research in the general fields of physical and chemical oceanography, marine geophysics and geology, either at sea or in laboratories and institutes having adequate facilities.

(c) from the Marshall and Orr Bequest for the support of marine biological research.

Grants may be used for periods up to one year, and are made on the understanding that university or other posts held by applicants will mean-while be kept open for them. Recipients are permitted to use grants while receiving salaries from regular appointments.

Applications are also invited for two one-year junior research fellow ships supported from the Maurice Hill Research Fund and the Marshall and Orr Bequest for applicants under 26 on 1 April 1982; these can be taken up any time between April and October 1982 and will be on the Society's Category D salary scale (currently £7,018  $\times$  £406 to £9.048 per annum with superannuation and national insurance).

In 1982 the total amounts available to be shared among all successful applicants will be about £9,500 from the Browne Research Fund, £15,500 from the Maurice Hill Research Fund and £17,000 from the Marshall and Orr Bequest; individual grants will not ordinarily be more than £1,500.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by 15 December 1981; applicants must state if they wish to apply for personal grants or for one of the junior research fellowships described above. (9862)E

## THE ROYAL SOCIETY JOHN MURRAY TRAVELLING STUDENTSHIP IN OCEANOGRAPHY AND **LIMNOLOGY 1982**

Applications are invited for the above Studentship, open to British graduates under the age of 35, for the encouragement of travel and work in oceanography or limnology. This award, which may be held for periods from three months to one year, will in 1982 be up to £2,000, adjusted according to qualifications and place and duration of research.

Applications are expecially invited from workers in oceanography and limnology, as well as in zoology, botany, geology, mathematics and physics, and it will be permitted to hold the award while receiving a salary from a regular appointment.

Applications receivable by 15 December 1981 should be made on forms obtainable from The Executive Secretary (BHM/UMAM), The Royal Society, 6 Carlton House Terrace, London SW1 5AG (9863)E

## **GRANTS**

## THE WELLCOME TRUST WELLCOME PROJECT DEVELOPMENT GRANTS FOR VETERINARY RESEARCH

The Wellcome Trustees announce their intention of making available in 1982, up to £150,000 for one or more Major Grants for the support of Veterinary Research to be carried out wholly, or in part, in a British University. The Grants, which may be held for up to five years, are intended to enable the expansion of an existing research programme along new and promising lines, or to promote the development of a separate project which could benefit from the expertise and resources currently devoted to research in a Department. The Trustees wish to maintain a degree of flexibility in the operation of these grants which may provide for research assistance and expenses, and essential items of equipment; the Grants are not intended to provide the personal remuneration of applicants.

The closing date for applications, which must be submitted on the appropriate form, is 1st March 1982.

Intending applicants are invited to address informal preliminary enquiries to Dr K B Sinclair, The Wellcome Trust, 1 Park Square West, London NW1 4LJ. (Telephone: 01-4864902). (9886)H

## **ANNOUNCEMENTS**

## 'SCIENCE AT THE CROSSROADS''

a meeting to commemorate fifty years of the British Radical Science movement.

Speakers

Margot Heinemann, Gary Wersky, Hilary and Steven Rose, Bob Young.

Friday, 20th November, 7.00pm Imperial College, Chemistry Theatre B Imperial Institute Road, SW7 Details: BSSRS, 9 Poland St, W1 (9853)G

## Prepackaged is nice. Pretested is critical.

These new assay systems are just that—systems. The matched components are pretested in a complete assay to make doubly sure they perform together as specified in the procedure. If the assay performance meets our highest standards, the system is approved for shipment and the results are included for your inspection.

Now you can forget uncertainties and concentrate on results. And save a lot of time and trouble, too.

## B-Adrenergic Receptor Assay System, [3H]-

- Identify β-adrenergic receptors in various tissue preparations.
- **Characterize**  $\beta$ -adrenergic receptor sub-types:  $\beta_1$  or  $\beta_2$ .
- Determine  $K_D$  and  $B_{max}$  values.

All necessary reagents are included, plus a detailed protocol for radioligand binding assays and data analysis. Contains a  $\beta$ -adrenergic antagonist tracer (dihydroalprenolol, [ ${}^{3}H$ ]-), a nonradioactive antagonist (propranolol), three nonradioactive agonists (epinephrine, norepinephrine, and isoproterenol), and dilution/assay buffer. In addition, turkey erythrocyte membranes are provided as a control, with the results of our in-house assay. The system is sufficient for twenty radioligand binding assays (400 tubes).

## eta-Lipotropin, [ $^{125}\Gamma$ ] - RIA Kit

- Determine human β-lipotropin levels in biological tissues and fluids.
- Highly sensitive.
- No detectable cross-reactivity with human β-endorphin.

All necessary reagents are provided for performing 250 assays, plus a detailed protocol. The  $\beta$ -lipotropin, [ $^{125}$ l]-tracer has high specific activity and immunoreactivity. The system detects low levels of  $\beta$ -lipotropin in the presence of such bioactive peptides as  $\beta$ -endorphin and methionine-enkephalin. Standard curve included with shipment.

 $\beta$ -Endorphin, [1251]-RIA KIT-Also available for the determination of human  $\beta$ -endorphin levels in biological tissues. Exceptional sensitivity, in the femtomole range.

Call us toll free to request detailed descriptions of any of these systems or to discuss any questions you may have for our technical staff. Not for use in humans or clinical diagnosis.

549 Albany Street, Boston, Massachusetts 02118 Call toll free: 800-225-1572 Telex: 94-0996 (In Massachusetts and International: 617-482-9595)

NEN Chemicals GmbH: D-6072 Dreieich, W. Germany, Postfach 401240, Tel. (06103) 85034, Telex 4-17993 NEN D. NEN Canada: 2453 46th Avenue, Lachine, Que. H8T 3C9, Tel. 514-636-4971, Telex 05-821808. Circle No.02 on Reader Enquiry Card.

# STERILE AIR AND YOU...

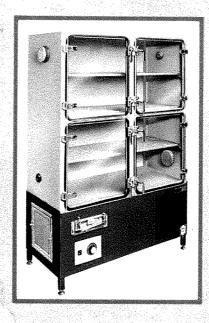

## INDEPENDENT ENVIRONMENTAL CABINET FOR ANIMAL STORAGE REF. E 110

This cabinet is intented for keeping (or breeding) different kinds of mice (Nude, S.P.F., germfree, gnotophoric, etc.). It makes it possible to isolate the animals in controlled environment separate from the surroundings, without effusing their smells into the premises.

It provides renewal of atmosphere and, at the same time, maintains a positive or negative pressure of clean air, by means of HEPA filter, in the storage space as required for the animals stored.

This unit can be fitted with up to 16 medium-size cages (approximately 200 mice). An additional module can be installed above or beside the base unit in order to double the storage capacity.

It is also possible to foresee an heating system for the fresh air entering the cabinet, using electrical resistance heating, interlocked with an electonic control system (sensitivity  $\pm$  0,5 °C).

## ENCEINTE AUTONOME D'ANIMALERIE RÉF. E 110

Cette enceinte est destinée au stockage (ou à l'élevage) laboratoire de différents types de souris (Nude, E.O.P.S., axéniques, gnotoxéniques, etc.).

Elle permet d'isoler les animaux en atmosphère contrôlée indépendante de l'environnement, sans répandre leurs od dans l'ambiance du local.

Elle assure silmutanément dans le volume de stockage, l' renouvellements d'ambiance et le maintien d'une pression positive ou négative, d'air propre (filtre HEPA), selon la spécificité des animaux stockés.

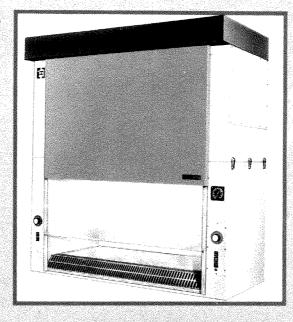

Cette enceinte peut recevoir jusqu'à 16 cages moyennes (200 souris environ). Un module supplémentaire peut êtri disposé au-dessus ou à côté de l'unité de base afin de de la capacité de stockage.

De plus, il est possible d'adjoindre un dispositif de récha de l'air neuf introduit dans l'armoire, constitué d'une résis électrique chauffante asservie à un système de régulation électronique (sensibilité  $\pm$  0,5 °C).

## "BIOHAZARD" VERTICAL LAMINAR FLOW HOOD. REF. PHENIX

10 Strategic points:

- 1 Noise level below 56 dBA.
- 2 Protection screen electrically controlled.
  - 3 Two H.E.P.A. filters.
- 4 Two centrifugal blowers, with variable speed.
- 5 Solid work surface, easily decontaminable, between two perforated stainless steel strips designed to take again the downward air flow.
  - 6 Air curtain created by an adjustable depression at the work surface level.
- 7 Uniform air speed intake on the whole length of the front aperture.
- 8 Made of welded aluminium with a particularly resistant protective coating.
  - 9 Certification of the efficiency control.
    - 10 Efficient After-Sales-Service.

Circle No. 05 on Reader Enquiry Card.

## HOTTE À FLUX LAMINAIRE VERTICAL "BIOHAZARD" RÉF. PHÉNIX

10 points forts:

- 1 Niveau sonore inférieur à 56 DbA.
- 2 Écran de protection à manœuvre électi
- 3 Deux filtres à très haute efficacité.
- 4 Deux ventilateurs à débit réglable.
- 5 Plan de travail plein, facilement décontaminable, entre deux grilles inox de reprise.
- 6 Rideau d'air engendré par une dépres réglable au niveau du plan de travail.
- 7 Vitesse d'aspiration uniforme sur tout longueur de l'ouverture frontale.
- 8 Construction en aluminium soudé ave revêtement de protection particulièrement résistant.
- 9 Contrôle d'efficience attesté par certifi
- 10 S.A.V. exceptionnel.

## **ULTROPHOR**

Put wavy bands where they belong. Among yesterday's problems.

Banish wavy bands with Ultrophor, a unique new instrument designed exclusively for professional electrofocusers by LKB, electrofocusing pioneers since 1960.

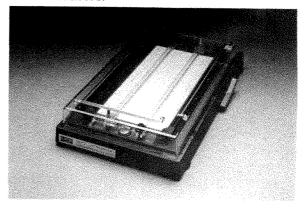

The ultracompact Ultrophor will cope with any analytical or preparative electrofocusing situation thanks to its radically new approach to electrode design, the construction of the highly efficient glass/aluminum cooling plate and the opportunity for atmospheric control.

The impressive list of bonuses include the flexibility of being able to run gels of any length up to 26 cm long or gels of any thickness, especially capillary-cast ultrathin gels, with less chance of wavy or skewed bands. The Ultrophor also has an unmatched capability to run high pH gels for sharp separations of alkaline samples as well as handle oxygensensitive or other labile samples.

Not only do you save valuable lab space with the compact Ultrophor but you save on time too because it's so fast and convenient to use and super-easy to clean. Like all LKB units, the new Ultrophor boasts a complete backup system and comprehensive technical support.

Contact your nearest LKB representative today for full information.

Ultrophor – the straight choice for professional electrofocusers.

## "Materials and Methods" S&S sets the standard

Key reasons researchers prefer S&S nitrocellulose, such as BA85, are its versatility and the fact that it is the material upon which the *entire* hybridization field is based. The first published report, in 1963, specified S&S nitrocellulose for filter hybridization. S&S nitrocellulose is still the accepted standard.

Now S&S nitrocellulose is used extensively in Southern (DNA) transfers, RNA transfers, bi-directional transfers, electrophoretic transfers, protein transfers, as well as plaque and colony hybridization studies. No other transfer medium has stood the test of time so well.

Another important factor behind the preeminence of S&S in the genetics field is the S&S policy of *total* commitment to the user. S&S understands the applications of nitrocellulose and provides technical assistance, comprehensive applications literature and the "Sequences" newsletters.

Photographed at the Institute of Cancer Research, Columbia University, Dr. Philip Feigelson's laboratory.

Moreover, 18 years of experience as a manufacturer of nitrocellulose enables S&S to guarantee product quality, lot after lot.

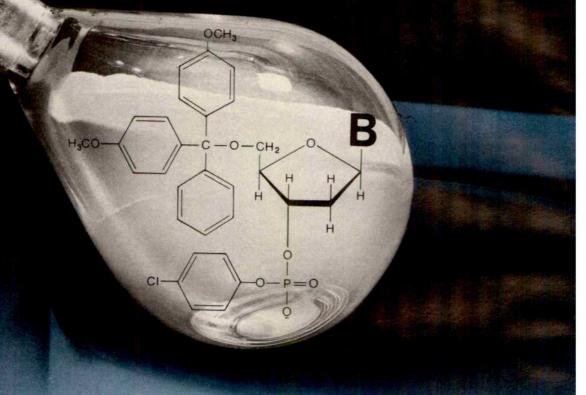

Publication of the basic transfer methods (as shown) is the latest example of S&S total commitment. Written by a team of leading molecular biologists, this 8-page guide details DNA, RNA and protein transfer techniques using nitrocellulose and Transa-Bind™ diazotized media. It is available free upon request from S&S, manufacturer of the recognized standard.

## Defined Sequence Oligodeoxynucleotides

## Easy synthesis in your own lab

Now construct oligodeoxynucleotides easily and economically using the soluble triester synthesis method and reagents from P-L Biochemicals.

P-L's reagents help you reduce synthesis time and costs with easier, faster synthesis right in your own laboratory. Plus, you get cleaner reactions, easier purification procedures and higher yields.

P-L has all the reagents you need in stock for prompt delivery.

- Barium salts of the 4 protected deoxynucleoside 3'-chlorophenylphosphates.
- 4 protected deoxynucleosides for 3'-termination.
- 16 protected deoxydinucleotides for speedier block addition.
- 16 protected 3'-terminating deoxydinucleotides.
- N<sup>4</sup>, 2', 3'-Tribenzoyl cytidine for terminating your synthetic oligodeoxynucleotide with a 3'-phosphate.
- Condensing reagents.

## **Rapid Custom Synthesis**

P-L Biochemicals will synthesize oligodeoxynucleotides at low cost...from 50 µg (about one A<sub>260</sub> unit) to grams. We use only highly purified reagents throughout. The sequence of your oligodeoxynucleotide is proven by established techniques. The complete absence of blocking groups is proven by exhaustive enzymatic hydrolysis and examination of the component nucleosides. Call Dr. Bill Gette today at (414) 347-7384 to discuss your needs and request a quote. You will be pleased at the low cost of our custom synthesis.

Whether you choose to synthesize your own oligodeoxynucleotides or have us prepare them for you, rely on P-L Biochemicals' 30 years of experience in nucleic acid chemistry for reliability, quality and economy.

### I lew curiace for cell culture

Now you can choose the most suitable microcarrier for your culture

Cytodex microcarriers bring new opportunities to

- routine and experimental cell culture
- production of viruses, interferon and other cell products
- in vitro studies on differentiation and metabolism

Cytodex 1

The microcarrier proven to be effective for growing more than 100 different cell types.

Especially developed for better yields of viruses and cell products. Retains all the advantages of Cytodex 1 with the added benefit of new charged groups necessary for cell attachment localized only on the surface of the microcarriers.

ytodex 3 The latest concept in microcarriers. The stable collagen surface gives improved attachment and yields of many cell types, especially those normally difficult to grow in culture. Enzyme digestion of the surface gives improved recovery and viability of harvested cells.

Make the most of your cell cultures. For more information on how Cytodex microcarriers give you new opportunities in cell culture contact us today.

Pharmacia Fine Chemicals AB Box 175 S-751 04 Uppsala 1 Sweden

# for fistimaturization

From detection of monoclonal antibodies, through specificity determination and purification from ascites, BRL has the reagents to enhance all phases of your hybridoma-based research.

#### Hybridoma Screening Kit

A complete system for the screening of hybridomas that secrete mouse immunoglobulins. The kit includes: β-galactosidase conjugated sheep anti-mouse IgG F(ab')₂, p-nitro-phenyl-β-D-galactoside as substrate, and complete protocol for use. In this enzyme-linked immunosorbant assay (ELISA), the second-antibody reagent has several advantages over alkaline phosphatase- and peroxidase-coupled antibodies: β-galactosidase is highly purified, and has a high specific activity. It is not present in most eukaryotic cells, and low background values are encountered when screening for cell surface antigens. Thus, sensitivity is enhanced. Also, p-nitrophenyl-β-D-galactoside does not show the potential carcinogenicity of other substrates used in ELISAs.

**BRL 9502 SA** 

#### **Immunoprecipitin**

Immunoprecipitin is formalin-fixed Staph A cells for the selective adsorption of IgG immunoglobulins. It specifically and tightly binds to the Fc portion of an IgG molecule and therefore will precipitate antigen-antibody complexes

BRL® Immunoprecipitin is subjected to rigorous quality control assays to assure you a reliable high quality product. Its features include: ■ High specificity and affinity for IgG immunoglobulins; 1 mg of Immunoprecipitin will bind  $\geq 8~\mu \mathrm{g}$  purified rabbit IgG  $\blacksquare$  High stability for at least four months when stored at 4°C ■ Complete elution of the antigen from the absorbant for both analytical and preparative purposes 

Complete protocol describing the removal of loosely bound proteins to reduce contamination of antigen by bacterial proteins

**BRL 9321 SA** 

#### Protein A Agarose

BRL® Protein A Agarose is an affinity matrix prepared by covalently coupling purified Protein A to agarose beads. Protein A binds to the Fc portion of IgG molecules without interfering with ability of the immunoglobulin to bind antigen. This specificity permits the single-step purification of IgG antibodies and some IgM and IgD classes. BRL® Protein A Agarose is distinguished by: Stability over a wide pH range (2 to 11) Compatability with strong denaturants like guanidine hydrochloride and urea Actual lot analysis to determine the amount of Protein A bound to the gel (1.8 to 2.5 mg/ml of gel), and the binding capacity for human IgG (8 to 10 mg/ml of gel)

**BRL 5918 SA**

## From DNA to RNA and beyond

These nine systems represent a major achievement in support of DNA/RNA research. They offer pretested, quality-assured sets of matched ingredients for analyzing genes and the products of their expression.

You could of course assemble the ingredients yourself, but here's what you'd likely be missing: Reliability, reproducibility, and hours of time better spent doing the research.

Call to discuss any questions you may have for our technical staff.

#### **Nick Translation**

Two exclusive systems for making consistently high specific activity probes using nick translation: dCTP, <sup>32</sup>P]- and dTTP, [<sup>3</sup>H]-. Both systems include E. coli DNA Polymerase I prepared in our laboratories to ensure reproducibility. The DNase I, dNTP mixtures, stop buffer, and sterile deionized water are optimized for compatibility and stability.

Systems sufficient for either 20 or 10 reactions contain the following:

dCTP,  $[\alpha$ -32P]-, or

dTTP, [methyl, 1', 2,'-3H]-

DNase I

DNA Polymerase I

Control Plasmid DNA (pBR322)

Deoxynucleoside Triphosphate

Mixture

Nick Translation Buffer Nick Translation Stop Buffer

Deionized Water

Each lot of systems is tested with the control supercoil pBR322 plasmid DNA to ensure efficient incorporation of dCMP or dTMP into DNA, and a copy of the curve is included with your system.

#### Ordering information:

NEK -004 (dCTP,  $[\alpha^{-32}P]$ ) (20 reactions, tracer in ethanol) NEK-004A (10 reactions, tracer in ethanol) NEK-004B (20 reactions, tracer concentrated in aqueous solution) NEK-004C (10 reactions, tracer concentrated in agueous solution) NEK-005 (dTTP, [3H])

#### 3' End Labeling

The system labels protruding (Hae II), flush (Alu I), and recessed (Hinf I) 3' termini generated from pBR322 with 3'-dATP,  $[\alpha^{-32}P]$ - (cordycepin 5'-triphosphate) in a simplified protocol similar to the procedures of Tu and Cohen. 1 The system utilizes terminal transferase to add a single 3'-dAMP,  $[\alpha^{-32}P]$ -molecule to the 3 end of a DNA chain. The resulting labeled DNA is suitable for sequencing by the Maxam and Gilbert<sup>2</sup> technique used in our new DNA Sequencing System (see next page).

The components include: 3'-dATP, [ $\alpha$ -32P]- (cordycepin

5'-triphosphate)

Terminal Deoxynucleotidyl

**Transferase** 

Terminal Transferase Reaction Buffer

Cobalt Chloride

Control Plasmid DNA Fragments **Deionized Water** 

Prior to shipment, all system components are subjected to a complete 3' end labeling procedure. The polyacrylamide gel used to separate the fragments is autoradiographed to assess labeling efficiency, and a copy of the autoradiogram is included with your system.

#### Ordering information:

NEK-009 (10-reaction system) NEK-009A (5-reaction system)

#### 5' End Labeling

Adapted from procedures describe by Maxam and Gilbert? an efficient, time-saving means of labeling nucleic acid fragments preparatory to DNA sequencing (see next column). The system includes ATP,  $[\gamma^{-32}P]$ - with polynucleotide kinase prepared in our own laboratories, and a carefully balanced complement of buffers, enzymes, and other reagents necessary for labeling the 5' termini of DNA fragments Systems sufficient for either 10 or 5 reactions contain the following:

ATP,  $[\gamma^{-32}P]$ -

Alkaline Phosphatase

Polynucleotide Kinase (purified to

homogeneity)

Phosphatase Buffer

**Direct Phosphorylation Buffer** Exchange Phosphorylation Buffer Hinf I Digest of Plasmid DNA,

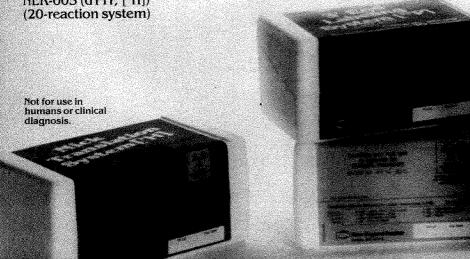

pBR322 (control to check system **Deionized Water** 

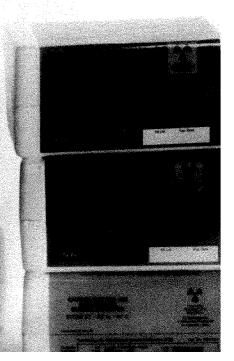

The system is tested the day before shipment using the same lots of components you will receive, including fresh tracer. The resulting autoradiogram is included with your system.

Ordering information:

NEK-006 (10-reaction system) NEK-006A (5 reaction system)

#### W NA Sequencing

s system follows the Maxambert procedure as published in thods in Enzymology and ludes the entire text of the arti
2 It is suitable for sequencing A labeled with our 3' or 5' End beling Systems and includes all igents necessary for the four se specific cleavage reactions. Ifficient material is provided for at st fifty of each reaction.

e following components are :luded: Imethyl Sulfate ydrazine iperidine iperidine Formate erric Chloride odium Hydroxide iaxam-Gilbert Procedure Manual

ch new lot of components is sted before shipment in a seence analysis of a DNA fragment. ie purity of each component is onitored using chromatographic alysis and documented for clusion with the system.

dering information: IEK-010

xam, A.M. and Gilbert, W., Methods in symology, 65 (1980)

## NEW **Transcription**

This system provides all the components necessary to perform eukaryotic cell-free transcription. It contains a cell-free extract derived from HeLa cells which catalyzes the synthesis of mRNA precursors when provided with an exogenous DNA containing a promoter for recognition by the polymerase. This RNA polymerase II dependent reaction is highly sensitive to the presence of  $\alpha$ -amanitin. The whole cell extract is prepared as described by Manley and coworkers.<sup>3</sup>

The system also includes UTP,  $[\alpha^{-32}P]$ - for labeling specific mRNA precursors. A control DNA template, the cloned Bal I-E restriction fragment of Adenovirus-2, has been used to optimize the system and is included with it. This control should be used by the investigator to determine proper functioning of the system.

Components sufficient for performing 50 assays (25 $\mu$ l reaction volume) are listed below:

UTP, [ $\alpha$ -<sup>32</sup>P]-HeLa Cell Extract Control DNA Template Transcription Cocktail Deionized Water

Ordering information: NEK-014 (50-reaction system)

<sup>3</sup>Manley, J.L., Fire, A., Cano, A., Sharp, P.A., and Gefter, M.L., PNAS (U.S.A.), **77:** 3855 (1980)

#### **Translation**

Now Proline [3H]

NEN's *in vitro* protein translation systems have made cell-free translations of eukaryotic mRNAs exceptionally reliable and reproducible. These systems are offered with either Methionine, L-[35S]- or Leucine, L-[3H]- or Proline, L-[3H]- labeled tracers. All three utilize an extract of rabbit reticulocyte lysate that has been treated with micrococcal nuclease to remove endogenous mRNA. The lysate is prepared under strictly controlled conditions to ensure retention of high protein synthesis activity.

The components include:
Rabbit Reticulocyte Lysate
Methionine, L-[3\*S]-, or
Leucine, L-[3,4,5-3H]-, or
Proline, L-[2, 3,4,5-3H]Translation Cocktail
Control mRNA
Magnesium Acetate
Potassium Acetate
Deionized Water

Each lot of systems is biologically tested with the control mRNA. A graph demonstrating Methionine, Leucine, or Proline incorporation is provided with your shipment.

#### Ordering information:

NEK-001 (Met [35S]) (100 reactions) NEK-001A (incl. extra ml lysate) NEK-001B (tracer shipped as needed)

NEK-002 (Leu [3H]) (100 reactions) NEK-002A (incl. extra ml lysate)

NEK-013 (Pro [3H]) (20 reactions) NEK-013A (100 reactions)

# The fraction collector that turns science fiction into science

Just a few years ago no one would have believed that a fraction collector like SuperRac could exist. Most researchers were used to their constant-volume and constant-time collectors – with level-sensors at best.

Many were resigned to a compromise between resolution and the efficient use of collection vessels.

SuperRac will change all that.

To begin with, SuperRac has built-in slope detection. Unlike a simple level sensor, it cuts peaks at their true beginnings and ends. You can even collect unresolved peaks in well-resolved fractions . . . and you never need to worry about baseline drift.

SuperRac also diverts uninteresting eluate to a waste trough - via a valve -

so you use fewer test tubes.

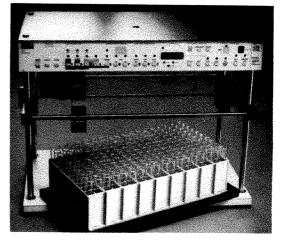

SuperRac's memory stores five different collection procedures that you can recall at the touch of a button. It has nine time windows allowing you to limit collection to interesting parts of your chromatogram.

SuperRac automatically compensates for asymmetric peaks and peak-width broadening during an isocratic elution. And it continues to run the pump for a specified time after a collection to clean and equilibrate the system.

Ask your local LKB distributor for more information on the new SuperRac. He'll give you several more reasons why we named it Super.

LKB

# NIKON S

#### **NIKON HIGH-PERFORMANCE** CF OPTICS. POSSIBLY THE FINEST **EVER AVAILABLE.**

INSTRUMENTATION Nikon Optiphot microscope with CF objectives.

#### SIGNIFICANCE

Nikon's revolutionary CF optics virtually eliminate chromatic aberration. Within this series, several high-performance objectives significantly extend observation powers.

#### SPECIFICS

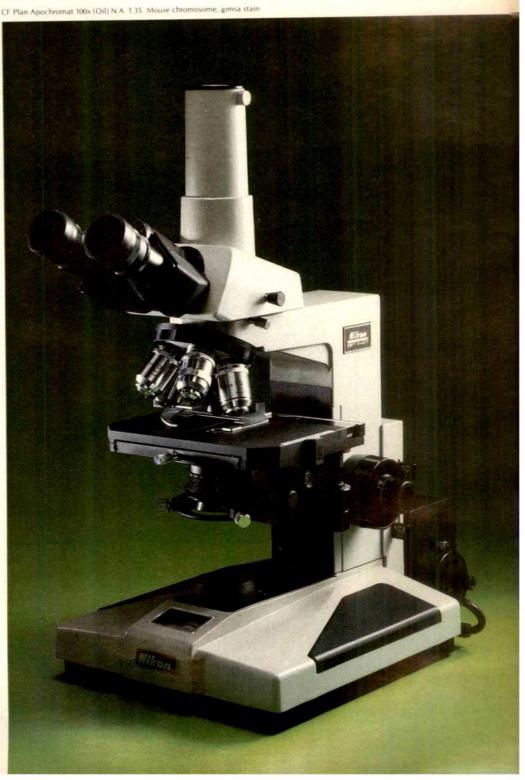

While all Nikon CF objectives provide a dramatic improvement in resolution, color rendition and contrast over the old compensation system, the following lenses are exceptional. The unique CF 2x plan apochromat has excellent image flatness for low power photography. The CF 40x plan apochromat, N.A. 0.95, dry, produces exceptionally bright, high-contrast images. Nikon's CF 100x NCG plan apochromat is designed to work without a cover glass. Its sharpness must be seen to be believed.

These remarkable optics are matched to a microscope body and illumination system equal to their performance the Nikon Optiphot. This totally new design is extremely stable. A standard 50-watt halogen Koehler illumination system covers all magnifications without need for adjustment, and the full range of Nikon accessories is available to match any assignment.

Extend your vision. Write: NIPPON KOGAKU K.K., Fuji Bldg., 2-3, Marunouchi 3-chome, Chiyoda-ku, Tokyo 100, Japan.

Nikon **Extending Man's Vision** 

Circle No.32 on Reader Enquiry Card.

10 years have passed since NISSUI successfully developed to get the patents of powdered tissue culture media in Japan which can be directly sterilized by autoclave.

NISSUI's most advanced tissue culture media offer you a convenient procedure for a large quantity to be autoclaved at once without destroying or inhibiting its supporting function for cell growth. NISSUI's media just meet today's needs such as in interferon research.

NISSUI, a pioneer of tissue culture, is working on further for important innovation.

NISSUI's powdered Tissue Culture Media Sterilizable by Autoclave include;

- **EAGLE MEM**
- RPMI 1640 MEDIUM ②
- EAGLE BME
- DULBECCO'S MODIFIED EAGLE MEDIUM 2

# Immunoelectrophoresis A new Pharmacia system for all occasions

#### Flexible

Immunoelectrophoresis and agarose zone electrophoresis in any size gel up to 114×225 mm.

#### **Fast**

High efficiency cooling plate permits high voltage runs powered by a 500 V/400 mA power supply.

#### Convenient

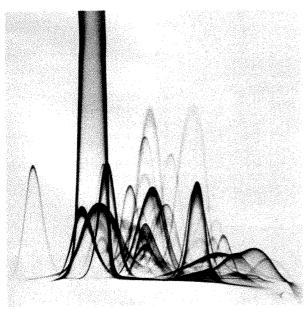

Removable buffer vessels allow easy remixing.

#### Complete

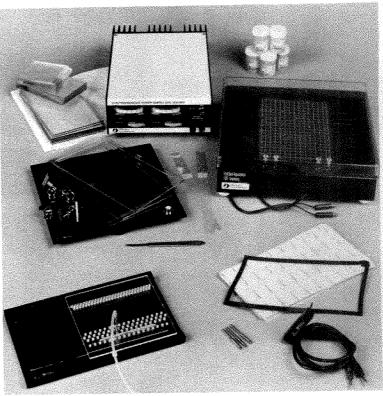

A full range of accessories for casting and punching gels.

#### Easy

A complete instructions/methodologies manual included to make any technique a simple task.

Pharmacia Fine Chemicals AB Box 175 S-751 04 Uppsala 1 Sweden

#### Agaroses for all occasions

Order

Type A Medium electroendosmosis for electrophoresis and most immunological techniques.

Type B High electroendosmosis for counter immunoelectrophoresis and diffusion techniques.

Type C Low electroendosmosis for crossed immunoelectrophoresis.

**Agarose IEF** A special grade for isoelectric focusing.

Send for complete information on the immunoelectrophoresis system for all occasions.

# Two Outstanding Solutions From A Well-Known Name Synonymous With Precision

In microscopy, what we see is of utmost importance. The sharper the detail, the better. And our findings should not only be visible through the viewing eyepiece. We should be able to document them quickly, easily and accurately on photographic film. Olympus, a well-known name in precision instruments, now offers outstanding solutions to both needs. The BH-2 System Microscope and the PM-10AD Photo and Cinemicrographic System. A superb combination that features the latest optical, mechanical and electronic advances. And best answers the diverse requirements of microscopy and photomicrography today.

#### **BH-2 MICROSCOPES**

The Modern Scientists' Choice.

To satisfy different user applications, the new BH-2 System Microscope is available in three different configurations.

Model BHS microscope is best suited for research and demanding clinical applications. It accepts a wide variety of modular accessories to ensure the highest system performance possible. A highly sophisticated model, it is perfect for photomicrography.

Model BHT microscope is suitable for research and training purposes. Space-saving and easy-to-handle, it features the same choice of accessories as the BHS.

Model BHTU microscope is especially effective for routine laboratory applications where observation of numerous specimens is required. It assures smooth handling and marking of all specimens.

#### LB OBJECTIVES

#### Indispensable Value That Makes The BH-2 Top-Of-The-Line.

Olympus is proud to offer a newly-computed series of LB (long barrel) objectives which offer increased working distance and the utmost in resolution, contrast, image clarity and flatness of field. In conjunction with the new 10x viewing eyepiece, these objectives provide a visual field of 20, the largest available for a conventional microscope.

What's more, a completely new and uniquilluminating system permits Köhler illumination, even with 1x and 2x objectives. In addition, 1x and 2x objectives are parfoc with 4x and higher power objectives.

#### PM-10AD

#### It Leaves Nothing To Chance.

The beauty of the PM-10AD Photomicrographic System is that it leaves no room for error. A built-in microcomputer ensures quick, accurate and fully automated photographic and cinematographic documentatio Exposure, 35mm film transport and compensation for reciprocity failure are completely automatic. A complete selectio of film formats and other advanced features are provided. Thanks to the clearly readabl LED digital display the programming and monitoring of various functions, e.g. timelapse photography, can be performed with a minimum of effort and experience.

# 'At last I've found the stereomicroscope that shows me everything in my speci

'I had a lot of difficulty finding the right stereomicroscope. At last, I found one from Wild Heerbrugg. It had to be one of theirs, because Wild Heerbrugg have a comprehensive range of stereomicroscopes. Also, because they know the practical problems from their experience of several decades and deal with these as no-one else can.

The accessories, too, are just right. These include a vast range of stands, illumination systems, etc. With these, I can get all the gations, from every type of specimen. And what never ceases to surprise me: the clarity, the contrast, the resolution and the colour fidelity obtained with a Wild stereomicroscope are simply unique. Just take a look for yourIntegrated circuit. Photographed with Zoom-Stereomicroscope WILD M 7S and Semiphotomat WILD MPS 15/11. Coaxial incident light and dark-field incident light.

Epimakroskop WILD M 450

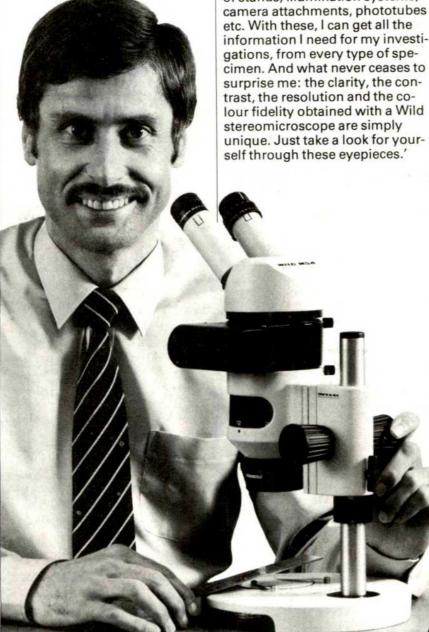

PS: Ask for your detailed documentation.

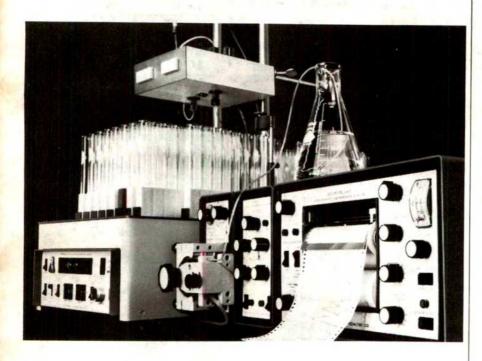

Yes, I am interested in Wild stereomicroscopes. Send your documentation to

Company

Send to: Wild Heerbrugg Ltd CH-9435 Heerbrugg, Switzerland or to your Wild representative.

#### Let an ISCO UA-5 monitor do it all for you.

Primarily, the UA-5 is a sensitive absorbance and fluorescence LC detector. But if you're a life scientist, it's much more than that: it's the key part of an integrated system, able to perform many functions in your lab.

Acccessories turn the UA-5 into a dual beam gel scanner or a fractionator for centrifuged density gradients. Drop-in cuvettes allow recording of certain reactions and take the load off your spectrophotometer for many routine jobs.

But the UA-5 is still the best

all-around column monitor: it offers you a built-in recorder. simultaneous monitoring of two columns or any two of 13 available wavelengths, automatic scale expansion, and the ISCO Peak Separator which controls a fraction collector to put each peak in its own tube

A versatile UA-5 costs no more than a single-purpose monitor. Learn more about what it can do for you: Send for your ISCO catalog today. ISCO, P.O. Box 5347, Lincoln, Nebraska 68505, U.S.A.

#### More muddle about nuclear weapons

Does the United States know what it is saying on nuclear strategy? Does it appreciate the consequences in Europe? Will it properly represent European interests at the arms control talks beginning 30 November?

The government of the United States lacks a way with words. So much is clear from the declarations of President Reagan and his Secretaries of State and of Defense in the past few weeks about the likely course of nuclear war in Europe. All three members of the Administration have let slip statements on this complicated issue which are dangerously over-simple. Have these high officials of state never learned to qualify simple declarative statements of policy with the conditional clauses that are usually necessary? Whatever the explanation, their gaffes have thrown a cloud over the negotiations due to begin in Geneva at the end of the month between the Soviet Union and the United States on European nuclear weapons. People in Europe, to say the least, are wondering whether officials so unsubtle in their use of language can be trusted fairly to represent the European case at these crucial talks.

The dispute two weeks ago between Mr Alexander Haig and Mr Caspar Weinberger about NATO's plans for demonstrating a nuclear weapon in some future crisis says more about personal relationships within the Administration than about the nuclear defence of Europe. On the Wednesday, Mr Haig was telling the Senate Foreign Relations Committee that NATO's contingency plans include one to "demonstrate to the other side that they are exceeding the limits of toleration". The following day, Mr Weinberger told the Senate Armed Services Committee that there is no such plan - nor "should" there be. Later, the White House announced that both secretaries were telling the truth. So, plainly, they are. What Washington now calls a "demonstrational" nuclear weapon must obviously be an option for NATO to consider if a conventional conflict should break out in Europe. On the face of things, such a device would be preferable to the use of nuclear weapons against targets on the ground. But it is virtually impossible to tell in advance when such a demonstration might be effective. What the Secretaries of State and Defense were talking about was what NATO calls the doctrine of "flexible response". They should have said so.

President Reagan's own slip of the tongue is more serious. In answer to a question from a group of newspaper editors three weeks ago, he said it is conceivable that some future nuclear war might be confined to Europe. Many Soviet strategists share this belief, even though Mr Leonid Brezhnev consistently denies it with gloomy accounts of how any nuclear war would visit destruction on the whole world. Mr Brezhnev is probably nearer the mark than Mr Reagan, for if by evil chance a single nuclear weapon is used in anger, there is no obvious stopping place on the ladder of escalation. Yet the NATO doctrine of flexible response supposes that a conventional incursion across the North German plain would have to be countered, after a few days, by "tactical" nuclear weapons. The hope is that this response would bring the incursion to a halt. If that happened, Mr Reagan would be right.

Yet this calculation is a gamble, and one with long odds. The strategists agree that the conflict would more probably escalate and that the United States would itself be drawn in. Precisely that probability is the foundation for NATO's strategic assumption that nuclear weapons are a peace-keeping device, a deterrent. Moreover, the argument works in both directions. The decision in 1979 that American nuclear weapons in Europe should be modernized by means of Pershing II and cruise missiles was intended by the then United States Administration to strengthen

the linkage between Western Europe and the United States. It is simply wrong of Mr Reagan to fail to point that out when speculating about the possibility that a nuclear war might be confined to Europe. The most serious damage done by his and his colleagues' remarks, however, is that Europeans' willingness to accept the theory of deterrence, by its nature bizarre, has been further undermined. Washington's willingness to talk about nuclear warfare as if it were just an elaboration of conventional warfare suggests that it does not understand what its strategy is for.

What does this imply for the talks beginning on 30 November in Geneva? At first sight, the prospect is not bright. Past experience, however, has shown that there is nothing more educative of the superficial understanding of politicians than negotiations about arms control. Six months from now, President Reagan and his colleagues will be wiser men, perhaps even regretting their delay in sitting down to talk. Moreover, it now appears that the United States has moved a long way to accommodate the anxieties of European governments about nuclear weapons. Last weekend, the Administration let it be known that its opening bid at Geneva will be an offer to dispense with Pershing II and cruise missiles (due to appear in Europe in 1983) if only the Soviet Union will remove its SS20 missiles (together with the older SS4 and SS5 missiles). The Soviet Union will predictably reply that the American offer says nothing about the French and British nuclear weapons. Sooner or later, one side or the other will acknowledge that aircraft cannot be entirely ignored. And the United States will have to decide what to do about Salt II.

Even so, the months ahead are potentially fruitful for the cause of arms control. Indeed, next year will also bring a special assembly of the United Nations on arms control, which could be valuable if states with only marginal interest in the subject can be prevented from making speeches about instant and comprehensive disarmament. There may also be a conference on arms control in Europe within the framework of the Helsinki agreements. It would make sense that the issue of a comprehensive ban on testing nuclear weapons should be given another airing, ideally as part of a Salt III, but the chances of that are slim - too much is at stake for the superpowers readily to agree. The potential beneficiaries of any progress in these directions are several. Many states, in Eastern as well as Western Europe, would welcome the civility and the greater political flexibility that further measures of arms control would bring. Even the superpowers, however, should benefit - President Reagan should be glad if part of his prospective budget deficit melts away,

There are, however, several potential snags. Just as negotiations on arms control are not merely better than no negotiations but are also in themselves a source of reasonableness, arms control negotiations that break down are a source of danger. The United States government has only itself to blame if its self-contradictions of the past few weeks have raised doubts about its seriousness, and its stomach for the tedium that lies ahead. More seriously, the proposal that the opening bid in the Geneva negotiations should abolish all potentially strategic nuclear missiles in Europe is likely, before many months have passed, to boomerang. The American missiles were, after all, intended as a guarantor of American involvement in European defence; will not their absence seem to many a proof of American detachment?

Nobody should be surprised if, some months from now, present anxieties about nuclear weapons based in Europe are outmatched by fears that, without them, one half of Europe or the other will be defenceless.

Finally, there is the problem — strictly, the red herring — of Mr Brezhnev's proposal for an international committee of distinguished scientists to consider the consequences of nuclear war and to tell the world what they are. In the past few months, the Soviet Union has introduced resolutions to this effect in the general assemblies of the World Health Organization and the UN Environmental Programme. By all accounts, a similar proposal will soon be put to the general assembly of the United Nations. In reality, however, there is no shortage of documents spelling out the horrors of nuclear conflict. Most of them agree that the consequences would be appalling. What is needed is not another chilling document but a more constructive attempt to show how nuclear war can realistically be avoided. While the scientific community has much to contribute to such an investigation, it has no special competence to say what is strategically and politically possible. But that, of course, is why the two superpowers are sending delegations to Geneva.

#### **Equity in research**

British research councils are saying that universities must also invest in research. But can they? And fairly?

The Medical Research Council has helpfully made public the letter in which it has told British universities that they need not apply for research grants on behalf of department which are inadequately equipped (see page 201). By this means, universities will at least know where they stand. And it is only right that a substantial grant-making agency such as the council, which is in principle well placed to compare the utility of money spent in university departments and in its own establishments, should do what it can to ensure that grants are not wasted because universities cannot give their recipients adequate support. One problem, of which the council must be well aware, is that in the process of saying no to applicants whose universities cannot support them properly, it may be denying good people a run for their money. For who can be sure that the academic departments which universities decide must be cut back will never include among their staffs potentially creative people? By doing what it must - concentrating support in the departments that universities themselves decide to back generously — the council (like other British research councils) is in danger of backing mediocre horses. This is another way of saying what has been clear all along — that the dual-support system (by which universities pay for the overhead cost of academic research, and research councils for the extras) has long since broken down. The question now is what should be done to put things right. To remark that a committee under Sir Alec Merrison has been brooding on the question for the past two years is not a sufficient answer.

The plain truth is that it will be intolerable (but also a dangerous waste of talent) if research councils such as the Medical Research Council think it prudent not to back particular people because the universities concerned have chosen to be mean to the departments in which those people work. The simple solution is obvious but probably unattainable — let the British research councils pay the full cost of the research projects that they back, transferring the cost of the overheads they would then incur from the budget of the University Grants Committee: the universities would kick up too much of a fuss. Another would be to consider grant applications from all university departments, and to use research council money to help ensure that successful applicants are able to migrate to places where research could be carried out effectively. The device now used in the Netherlands (see page 202) by which universities are subsidized under the two separate headings of teaching and research would be even less welcome to British universities — but, on that account, might be an efficient spur to change. Whatever stratagem is used, there is a crying need that something should change. For to be unable to make research grants to people likely to use them well is not merely inequitable to those concerned but unfair to the rest of us.

#### Come back, Columbia

The shuttle looks like a success. Might it be a better one if NASA had time to think?

The second test-flight of the shuttle spacecraft was in no sense the near-calamity it has been represented to have been. That one out of three fuel cells should have functioned inefficiently, but that the spacecraft should nevertheless have performed well for more than two days, can just as well be taken as a proof of the good sense of its designers and of the flexibility of the system they have devised. It is not as if the shuttle were simply another kind of aircraft, whose development would no doubt have followed a more conventional course, with a succession of test-flights gradually extending its performance. Instead, it has gone almost in one jump from the drawing-board to full flight. In the steady enlargement of the regimen accessible to manoeuvrable passenger-carrying vehicles, the shuttle is a landmark of an innovation. Two years late though it may be, the US National Aeronautics and Space Administration deserves full credit for making it fly at all.

Two groups of problems nevertheless persist. First, the cost of the remaining development threatens to be an insupportably large fraction of the total space budget, with the result that NASA cannot sustain its modest interest in the less spectacular parts of its research programme even though it has been shielded from the full rigours of the 12 per cent budget cut decreed last month. It

cannot be that this is what the White House intends. And even though the potential military importance of the shuttle has led some to suggest that the Pentagon might shoulder some of the responsibility for it, its importance as an economical means of launching satellites of great commercial importance is, rather, an argument (if one were needed) that budget-balancing by means of across-the-board cuts is no way to conduct government business. But there are also problems with the shuttle itself, last week's success apart. Now, not later, is the time to be sure that solutions adopted ten years ago to technical problems such as the heating of the spacecraft in the upper atmosphere are still the best.

The important need, now, it to get the shuttle right. The United States space administration is understandably anxious not to delay much more. The customers are restive, and the political dangers for an agency that fails to deliver could be serious. But, to many people's surprise, space travel in the modest mould represented by last week's Columbia has come to stay. It will be economically important and, in the long run, a cheerful influence on people's spirits. The space agency will no doubt say that all the technical problems — the engines, the heat shield, the turn-round time and the next rocket stage — are continually being looked at. It would be best if this re-examination could be comprehensive, and public. For then the pressures from would-be customers, at the Pentagon and elsewhere, would be diminished. As would the risk of losing great benefits for want of a little forethought.

## US plans help for nuclear industry

# Civil power to link with weapons?

Washington

The Reagan Administration has offered the US nuclear industry all of the moral — and some of the economic — support that it wants. But even this may not be enough to restore the industry to health according to the parting words of the Nuclear Safety Oversight Commission (NSOC), an independent advisory body set up by President Carter following the Three Mile Island accident in March 1979.

Three main options face the Administration if it wants to save the civil nuclear industry, according to Governor Bruce Babbit of Arizona, chairman of NSOC. He presented President Reagan with this opinion when transmitting the commission's final report last month. Babbit warned, however, that each of the options would require a high political price.

The first option would be to regionalize the nuclear industry and draw it into the public power grids, a form of seminationalization already adopted, for example, by the Tennessee Valley Authority. The second would be to bail out the industry directly through government subsidies, although allowing it to remain largely in private hands.

The third and perhaps most controversial option would be to re-establish links between the commerical uses of nuclear power and the military demands for nuclear weapons, using the expansion of the latter to sustain the former. Some critics argue that the Administration's plan to use plutonium extracted from commercial wastes to provide fuel for weapons is already a step in this direction.

This drastic set of choices reflects the serious problems facing the industry. The most popular scapegoats have been the tough environmental regulations and stringent licence review procedures; but no less important has been the reduction in the rate of growth in power demand from 7 to 3 per cent a year over the past decade, and continued public concern about safety (highlighted by the design mistakes found in the Diablo Canyon reactor under construction in California).

The Administration has already taken several steps to assist the nuclear industry. In an attempt to encourage nuclear exports, for example, it is offering countries such as Mexico cut-price enriched uranium, and scientific collaboration in areas such as waste disposal and reactor safety.

Other measures are being taken to speed

up the licensing of new plants. In a policy statement issued last month, Mr Reagan listed the goal of reducing the time needed to license and operate a new nuclear reactor from an average of 12 to 7 years as one of five steps intended to revitalize the nuclear industry (*Nature* 15 October, p.505).

Congress is likely to be sympathetic. Two weeks ago the House of Representatives passed a bill that would allow utility companies to start initial low-level operations of a new nuclear plant even before all local complaints had been fully heard. A similar measure, now before the Senate, is expected to pass with little difficulty.

The economic and safety problems facing the industry are unlikely to be resolved as simply. In the past few months several local utilities have decided to abandon plans for new reactors. In several cases, such as the Pilgrim II plant which was to have been built by Boston Edison Co. on the Massachusetts coast, construction delays and the need to incorporate new safety requirements have increased initial estimates of construction costs by about a factor of ten.

Many industry supporters feel that, in view of growing consumer opposition to the rapidly escalating electricity bills to

Waiting at Diablo Canyon

finance such construction — in some cases increasing by 500 per cent within a few years — the only way for the industry to remain viable is through a massive infusion of federal funds. But this possibility is already coming under fire from both sides

#### Irish veterinarians in dog-house

Brussels

A report by the European Commission on the eradication of cattle diseases has levelled an accusing finger at the Irish veterinary profession. Since 1965 about £90 million has been spent by the state on eradicating bovine tuberculosis in Ireland but, says the Commission, "there has been no change in the bovine tuberculosis situation in Ireland".

"It should not be concluded that this lack of progress is due to any lack of finance (£11 million was spent in 1980) but rather to the fundamental fact that twothirds of the reactors are being missed at annual round testing" continues the report. The Commission does not accuse anyone of cheating. It does, however, draw a comparison with the results obtained during the early 1970s by about 50 temporary veterinary inspectors employed by the Department of Agriculture to carry out tuberculin tests on a random sample of herds that were normally assigned to local veterinary surgeons for testing. The inspectors tested about 18 per cent of the national herd over several years and found approximately three times as many infected animals and herds as had the vets.

It would, of course, be to the farmers' advantage to avoid having their animals identified as being infected as this would involve high costs. Apart from the restrictions on the movement and sales of the animals and the need for proper handling

and isolation facilities, the amount of compensation paid for slaughtered beasts does not match full market value, in contrast with the situation in the United Kingdom.

Faulty testing schemes may be the answer and the European Commission, which is proposing to continue with its accelerated programme to eradicate brucellosis, tuberculosis and leukosis in the EEC, is threatening to cut off disease eradication funds to Ireland unless testing procedures are improved.

The EEC's contribution to the shared costs of accelerating the eradication of these diseases is some 130 million European Currency Units (about £65 million) over the past three years. The Commission confidently reports that by 1983 at the latest, all EEC heads will be under control as far as brucellosis and tuberculosis are concerned. By the end of the current programme, it is estimated that 1.5 million animals will have been destroyed.

Enzootic bovine leukosis will almost certainly be eradicated in Denmark in the near future and the disease is well under control in Germany. France and the United Kingdom have not availed themselves of EEC funds to eradicate leukosis. The Commission also studiously avoids contributing to the debate in the United Kingdom on the badgers and tuberculosis issue except to say that the disease has been practically eradicated there.

Jasper Becker

of the political spectrum.

The Administration has already agreed to support a federal contribution of \$123 million towards the almost \$1,000 million which it is estimated will be needed to clean up the Three Mile Island power plant. Private utilities have agreed to contribute a similar amount through the Edison Electric Institute, and the rest of the money comes from insurance cover and from the states of Pennsylvania and New Jersey.

The extra costs of new plants is not merely a result of licensing delays. As safety questions come under scrutiny, embarrassing facts are beginning to emerge. At the Diablo Canyon plant in California, for example, the wrong blueprint had been used to calculate potential stresses arising from an earthquake. And almost all of the operating nuclear plants across the country are likely to miss the deadline imposed by the Nuclear Regulatory Commission for replacing between 15 and 40 per cent of their electrical equipment which had previously been thought safe, but which was shown to be liable to failure under exposure to steam and radiation that might occur during an accident.

Such design errors have played into the hands of anti-nuclear protesters who claim that nuclear technology must remain under strict control and supervision. The industry claims that it is being strangled by these controls; but, especially at a local level the courts have tended to back up the critics.

These developments appear to foreclose all but the final NSOC option — that of increasing links with the military sector, perhaps through the recreation of the Atomic Energy Commission which shared responsibility for the military and civilian uses of nuclear fission until the early 1970s. Department of Energy officials, for example, are already claiming that their initial proposals to extract plutonium from commercial wastes through laser isotope separation (*Nature* 30 July, p.401) could partially solve the storage problem.

Here again, however, the political problems are likely to be enormous. Critics argue that allowing the military greater leverage over the civilian programme could threaten attempts to control nuclear technology through more democratic means, and that it would conflict with efforts to limit the proliferation of nuclear weapons in developing nations by trying to divorce the civilian and nuclear aspects of nuclear energy.

Nobody in Washington pretends that finding the solution will be easy, President Reagan has asked Energy Secretary James Edwards and the director of the Office of Science and Technology Policy, Dr George (Jay) Keyworth, to consult industry, the utilities and universities, and they have been given almost a year to prepare a report on "obstacles that stand in the way of increased used of nuclear energy and the steps needed to overcome them".

David Dickson

#### Human growth hormone

#### **Shortage persists**

British supplies of human growth hormone are in danger. Over-optimism about the availability of the hormone from genetically engineered bacteria combined with a failure to appreciate that even mortuary workers are human has left the United Kingdom's National Health Service with supplies which are inadequate for the optimal treatment of the 800 British children with growth hormone deficiency.

Until biotechnology raised the prospect of an alternative, the only source of human growth hormone was the pituitary glands of cadavers. Three years ago at least 50,000 pituitary glands were collected from mortuaries in hospitals and processed in Cambridge. Another 20,000 pituitaries were collected from public mortuaries for processing in London. The combined operation, under the auspices of the

#### Two heads for one

The Centre National de la Recherche Scientifique of France now has its complement of two heads, a directorgeneral and a president, just two weeks after the previous incumbents resigned on a matter of principle. First — as reported last week — the mathematician Jean-Jacques Payan has been appointed director-general; and now M. Claude Frejacques, present director of the Délégation Générale à la Recherche Scientifique et Technique (DGRST) has been appointed president.

The appointments may be interim ones, as the Minister of State for Science and Technology, M. Jean-Pierre Chevènement, is said to prefer a single director for CNRS, rather than the dual headship established by the previous administration. But there was no time to change the constitution before the national colloquium, due in January, where major policy issues will be thrashed out in public, and CNRS—as the major supporter of basic research in France—has to have a clear voice by then.

Nevertheless, the appointment of Frejacques, a career civil servant rather than a scientist, has its rationale. DGRST was effectively administration of the previous - and less powerful - science minister, Pierre Aigrain, and Chevènement has begun to set up almost a rival administration in his new ministry. DGRST may in the end be disbanded in all but name, with its parts becoming wings of the research ministry. Chevenement already has a chef du cabinet, so some role had to be found for Frejacques. CNRS seemed to suit - now leaving the minister free to shuffle DGRST as he Robert Walgate wishes.

Medical Research Council, would have produced more than enough growth hormone for British needs so that up to half of the pituitaries from hospital mortuaries were stockpiled. Because of a drastic fall in the collection of pituitaries from hospitals, the stockpile is now depleted. Faced with a huge rise in cost of the hormone, the Department of Health and Social Security (DHSS) has now ordered a reduction in therapeutic dosage during 1982.

Trouble began when DHSS took over the collection and processing of pituitaries. Most of the hospital pituitaries were to be processed in the department's new Centre for Applied Microbiological Research at Porton Down. Material from public mortuaries, on the other hand, was to be handled by the Swedish company Kabi Vitrum, chosen because it has the European rights to manufacture and market human growth hormone from bacteria genetically-engineered by the Californian company Genentech. Bacterial growth hormone was to have been provided by Kabi Vitrum to DHSS at a preferential price as soon as British clinical trials, due to start in January 1981, had been successfully completed.

The first snag with these plans was that DHSS decided to use the changeover as an opportunity to consolidate into the wages of mortuary workers at hospitals, the small sum that had previously been paid to them for each pituitary collected. As many a manager might have told DHSS, consolidation can be a recipe for diminished productivity. The number collected from public mortuaries has fallen to about 13,000 a year despite the reinstatement of the special payments, but was never more than 20,000. The combined annual collection of pituitaries has therefore fallen by 60 per cent and now provides less than half the amount of hormone needed to treat British children.

The shortfall has been exacerbated by a delay in the production of bacterial human growth hormone. The first batch of Genentech's hormone to be given to humans had unacceptable side effects (fever and the lysis of blood monocytes) and full clinical trials had to be postponed. The side effects were almost certainly due to the presence of bacterial toxins in the hormone preparation, and both Genentech and Kabi Vitrum have now developed a more complex purification process. Genentech claims that its cleaner preparation has cleared toxicity tests and says that it is already six weeks into a clinical trial on children. Kabi Vitrum is slightly behind, having just completed a toxicity trial in Sweden.

Some, however, doubt whether the bacterially-derived human growth hormone will pass through its clinical trials successfully. The scepticism is based on the fact that the bacterial hormone is not quite identical with the authentic human hormone. Clever though Genentech's genetic engineers are, they have not been

able to devise a way for their bacteria to produce growth hormone without an extra methionine at one end of the molecule. This amino acid, say some hormone biochemists such as Dr Philip Lowry of St Bartholomew's Hospital, is a prime target for recognition by antibodies. He therefore predicts that when used in long-term therapy, bacterially-derived human growth hormone will provoke an antibody response that will preclude its clinical use.

It is too soon to know whether Dr Lowry's predictions are right. If not, Kabi Vitrum bacterial growth hormone should be available to plug the gap in Britain's traditional supplies before dosage has to be too seriously reduced. The reduction already planned is considered not to be disastrous; one expert reckons that at worst the children so treated would end up no more than three centimetres short of their maximal height.

Because there is a world shortage of the hormone there is little hope that DHSS will find alternative supplies. And even if it could, the cost would probably be prohibitive. One estimate is that 3 years ago, the cost was £1.25 per 5-unit ampoule whereas an equivalent ampoule purchased by DHSS from Kabi Vitrum now costs £15.

Peter Newmark

#### UK medical research

#### To those that hath...

British university departments asking the Medical Research Council (MRC) for research grants will now need an assurance of financial support from their universities. MRC's chief concern is that universities, in adjusting to their own reduced budgets, may starve individual departments of funds, with the result that its research grants are "rendered ineffective".

In a letter to universities this month, the council reaffirms its belief in the dual support system, under which British university departments winning grants from research councils are supposed to be maintained as "well-found laboratories" out of the general subvention from the University Grants Committee. It acknowledges, however, that there may be temporary difficulties, as when universities decide to freeze vacant posts.

The move is MRC's attempt to force the universities' hands. Like the Science and Engineering Research Council, it is concerned that the quality of university research will be irreparably damaged if universities spread their dwindling resources too thinly. Hence it will support the objective of the University Grants Committee (UGC) that universities should concentrate their own resources on good departments considered worthy of support. Applicants for new grants from institutions not favoured by UGC may be in for a raw deal.

The MRC, nevertheless, offers some help to universities. Researchers who lose their jobs, for example, will be eligible for small personal grants, which, while not paying their salaries, will help them complete projects already started. Universities are also invited to nominate exceptionally promising researchers who may be eligible for help. MRC is willing to expand its senior fellowship scheme which provides support for up to ten years for promising young researchers unable to find tenured posts. Demand for the scheme, which has been running for four years, is already heavier this year than in the past. MRC is also willing to increase the number of awards it makes under existing schemes which free academics from teaching and administrative tasks to allow them to spend a few years on full-time research.

The release of the MRC letter to the universities last week coincided with publication of its annual report for the year ending March 1981 (HMSO £4.00). According to the report, the council has resolved its long-standing dispute over the terms of employment of researchers on short-term contracts. The council has agreed that 70-80 per cent of its posts will carry tenure, compared with 67 per cent previously. Short-term appointments will now be almost exclusively for three years and open competition will be invited for tenured positions. The new scheme will not cost the council more, according to Dr James Gowans, Secretary of MRC, chiefly because it does away with appointments of intermediate term.

During 1980-81, the council spent nearly £93 million, about £15 million of which was transferred to its budget from the Department of Health after the collapse of the Rothschild customer-contractor principle. Under the principle, first introduced in 1974, money was transferred from the council's annual budget to government departments for spending on research commissioned through the council. The new policy, however, has made little difference to the council's work, according to Dr Gowans, because the health department chose to commission long-term research which the council will continue to support. In the deal struck with the health department, the council has agreed to increase support for health service research to £2 million by 1985-86.

The year to March 1981 was not easy the council had to supplement its government grant with £500,000 of its own money and was not able to provide all the support for top quality research for which it was asked. But Dr. Gowans's chief concern is for the future. In particular, he fears that the government may renege on its earlier promise to maintain the real value of the science vote to be announced in December. The implications of a real budget cut for MRC, which in any one year has more than 90 per cent of the its budget tied up in on-going commitments, could be far-reaching, involving a reduction in the amount of research it supports in universities. Judy Redfearn European Science Foundation

#### Signs of solidity

Strasbourg

The European Science Foundation (ESF) — Europe's fledgling international academy — appears to have come of age. Last week the foundation, representing 47 research councils in 18 countries, made its first direct approach to governments with a letter to research ministers requesting them to take up the idea of a "European Synchrotron Radiation Source", a £30 million third-generation source of X-rays for Europe.

The new source is considered necessary by most European X-ray users if Europe is to keep abreast of American competence in the field. But the foundation's request is significant not only for its content but as an example of the foundation's new confidence in the practical role it can play in Europe.

The foundation has previously been cautious of its role vis à vis its member research councils, but there seems to be such agreement among the various councils over the synchrotron source, such a need to cooperate financially in the present recession and such growing confidence in the foundation's offices that the members are willing to let the corporate ESF approach go ahead.

Professor Hubert Curien, the French president of the foundation, makes it clear in his letter to the ministers that ESF—as a non-governmental organization—cannot handled political questions such as the site for the source or the national contributions to its cost, but requests governments to set up a committee of representatives to do just that. The governmental committee would then work at arm's length from the foundation, "seeded", as it were, by the foundation's earlier enthusiasm, hard work and the now-detailed specification of the X-ray machine.

How governments will respond is yet to be seen, but already several countries and organizations have made unofficial offers of sites, the most detailed of which has come from Italy (for Trieste). The ESF committee has also made a careful study of the possible use of a tunnel at the European Centre for Nuclear Physics (CERN) near Geneva, which now holds the intersecting storage rings, a ten-year-old device likely to be closed within a few years to save money for the large electron-positron collider (LEP). If the new X-ray source were built at CERN it would, however, come outside the CERN budget.

According to the foundation's optimum timetable, the intergovernmental committee would meet early in 1982; governments would take a decision in principle in early 1983; and the source would be in operation by 1988-89.

The foundation also agreed last week—at its annual assembly in Strasbourg—on a serious study of what may be its next big project—a "geotraverse" of Europe. This

would entail a detailed geological survey down to the mantle, using every available technique, of a band 2 to 20 kilometres wide stretching from the North Cape in Norway to North Africa, across the many major ancient geological boundaries of Europe.

The exercise would be a continental parallel to the International Deep Sea Drilling project and would cost around £3 million over seven years, 2-3 years of which would be used to gather data. The Swiss national research council will pay for a pilot study.

On a smaller scale, the foundation has decided to set up a new fellowship scheme this for toxicologists - similar to its existing European Training Programme in Brain and Behaviour Research. Each year £70,000 will be made available by council in nine countries (Denmark, Finland, Ireland Italy, The Netherlands, Norway, Sweden and the United Kingdom) for short-term and long-term fellowships in toxicology. The object is to stimulate research on the toxicology of environmental chemicals and to help increase the number of experts in Europe who could advise governments and industry. The first fellowships will be advertised next spring to be available in autumn 1982. **Robert Walgate** 

#### **EEC Research Council**

#### **Broader future**

Brussels

EEC's ten research ministers have finally approved the first stage of a biomolecular engineering programme and the 4-year programme on microelectronics (worth \$40 million). This agreement, reached at a meeting on 9 November, reflects the future attitude of the Community to research and development.

The European Commissioner for industry and now research, Etienne Davignon, sees research and development as being one of the prime vehicles by which Europe's flagging industrial competitivity compared with the United States and Japan can be revived. That his ideas are being taken seriously by member states is demonstrated by the council's decision to go ahead with biomolecular engineering and microelectronics programmes.

Only the first stage of the 4-year programme (indirect action) on molecular engineering has been agreed. The original six comprehensive projects proposed by the commission still stand, but the whole programme will now be focused on agriculture and on safety and environmental questions. So for two years and with about \$8 million to spend on 50 per cent support, the commission will fund research on, say, the synthesis of vaccines and pesticides of importance to European agriculture; on the biotransformation of agricultural surpluses and wastes; and on plant molecular genetics and gene transfer. The safety work - accounting for 20 per cent of the grant — will cover the detection of contaminants in industrial microbial strains and the extension of risk assessment procedures.

After two years, the programme will be re-assessed and if successful continued — probably with a further injection of cash. The commission hopes to call for tenders around the end of this year, and the programme will start in earnest on 1 April 1982.

The commission's 4-year action programme in microelectronic technology is the second arm of the strategy to stimulate European research into telematics and informatics. A programme has been under way since September 1979 on data processing and a third programme on telecommunications is expected to be proposed before the end of 1981. The agreed budget is for \$40 million, \$12 million less than was originally asked for.

This programme is also important because member countries have agreed to coordinate their activities and keep each other informed of new developments to ensure that a microchip production industry is soon established in Europe.

Figures from a report being prepared on the competitivity of European industry illustrate the struggle facing Europe. Jobs created in Europe between 1970 and 1980 numbered 2 million compared with 19 million in the United States and 5 million in Japan. Japan spends globally half as much money on research as EEC, but Japanese researchers register four times as many patents.

In the field of microprocessors, EEC is calculated to have spent \$470 million developing chips compared with Japanese expenditure of \$240 million. But Japan and the United States each supply 40 per cent of the world microprocessor market, while European production accounts for less than 10 per cent.

The commission's desire to coordinate research efforts carried out at national levels would involve holding regular twice-yearly meetings to plan and exchange information and analyse national spending. By discussing programmes at the early stages, overlapping and duplication could be avoided and lead to an efficient dissemination of research results both among the member states and between universities and industry. Using Euronet as an industrial data base and the planned INSIS integrated numerical network, the gap between research and industrial application would be narrowed.

For the Community's joint research centres, Davignon foresees the scope of the research being widened — a move that might involve the opening of the centres to agricultural research for the African, Caribbean and Pacific countries linked to EEC by the Lomé convention. The concept of promoting "centres of excellence" is also being discussed.

Agriculture research will also be boosted. Only 1.1 per cent of EEC's

research budget is devoted to this field despite the vital role the Common Agricultural Policy plays in EEC affairs.

Although the commission seems to be backing the argument that increased research and development is a means of solving current economic problems, a belief supported by European industrialists, ministers were non-committal on Davignon's request to double between now and 1986 the amount of money from the Community budget actually devoted to research and development.

Jasper Buker

#### Netherlands universities

#### Misery ahead

Ending several weeks of uncertainy the Netherlands government announced on Monday the latest forward plan for the universities. Briefly, the Ministry of Education and Science is looking for a 2 per cent cut in university salary budgets in the vears 1984 and 1985, together with a 3 per cent cut in other expenditure. Although the percentage reductions of the university budget (expected to save a total of 75 million Dutch guilders (£16.5 million) a year) are not at first sight large, coming as they do after several years in each of which university budgets have been reduced by 3 per cent, the consequences could be serious.

In the two years ahead, the ministry has also decreed that there should be a freeze on academic vacancies. During that period, the ministry also hopes that there will be a rationalization of the structure of university departments, with resources concentrated in the stronger departments. The Academic Council, which advises the ministry, has already begun to put individual departments in order of merit. It is possible that if the universities concerned do not take the initiative in reorganizing themselves, the minister will provide an incentive by adjusting the grants they are offered in the years ahead, either up or down.

One curious features of this week's proposals is that the government expects the universities collectively to pay their bills less promptly. The result may be that the drain on the government's cash resources is reduced by up to 40 million guilders in 1982. The reactions of the universities' creditors are not yet known.

On the face of things, there will be no immediate need of redundancies among academic staffs, although the ministry has set up a central register of vacancies. Even during the two years ahead, universities will be free to apply for a dispensation to fill vacant posts considered essential to their academic or research programmes. There is, however, a possibility that some universities will prefer to reduce their staffs than to stomach for a further two years the acute shortage of disposable income from which they have been suffering.

The next step will be for the parliament

in the Hague to approve the two university budgets — for teaching and for research — now proposed. Further support for research projects is provided by the Netherlands research council (ZWO) whose financial importance in university affairs has been increasing in recent years.

However, ZWO will have to do without a science minister — a post established only eight years ago. The previous minister, Anthonius van Trier, was without portfolio, but he badgered his ministerial colleagues into giving him control of substantial parts of their budgets. The new government has removed this irritation, the support of science reverting to the new minister of education, Josephus van Kemenade. And as Kemenade's major political interest is in establishing comprehensive education for Dutch schoolchildren, scientists in the Netherlands are worried.

#### Agricultural research

#### **Changes mooted**

Washington

"Reach out and touch somebody", the slogan being used in the United States to promote the use of long-distance telephone calls, has also become a newly-prominent policy theme for the thirteen agricultural research institutions which constitute the Consultative Group for International Agricultural Research (CGIAR).

The group is an informal network organized under the auspices of the World Bank through which developed countries, multilateral agencies and private foundations channel their support for research at the institutions into developing countries' agricultural needs.

At their annual meeting in Washington last week, both donors and research administrators endorsed current efforts by the institutions to increase linkages with outside research workers in two directions. One is to strengthen collaborative research projects with universities and other institutions in developed countries, in order to make the best use of present scientific knowledge. The second direction is to improve links with national agricultural research programmes in the developing countries.

It was the tenth annual meeting of the group, which has grown from four to thirteen members since it was founded in 1971. Since then, the total amount of funds channelled through the CGIAR system has risen from \$20 million to \$135 million.

In the past few years, however, as the rate of inflation has crept upwards, the growth of the institutes in real terms has begun to slacken off. Last year, for the first time, several institutes had to trim their programmes when it was realized that with various industrialized countries — and private institutions — cutting back on their aid programmes, voluntary contributions would not meet the targets.

#### Sowing more seeds

Mexico City

One of the biggest and best known of the research centres funded through the Consultative Group on International Agricultural Research (CGIAR) is the International Maize and Wheat Improvement Center (CIMMYT, after its Spanish initials), whose headquarters nestle in foothills on the edge of a high, fertile plain thirty miles north of Mexico City.

Based on a programme initially set up by the Mexican government and the Rockefeller Foundation in the early 1940s, CIMMYT was formally established as an international centre in 1966, and was one of the four founding institutes when CGIAR was created in 1971. Its current budget makes the largest financially of the 13 centres which now constitute the group.

In terms of its initial mission — the use of scientific breeding techniques to increase the yield of wheat and maize crops — CIMMYT has been spectacularly successful. It is known internationally as the home of the Green Revolution, due to the high-yielding varieties of dwarf wheat for which its most famous scientist, Dr Norman Borlaug, was awarded the Nobel prize. Among its more recent success stories is Bangladesh, which has increased its wheat yield from 114,000 tons in 1975 to 1.2 million tons in the current year.

But times are changing at CIMMYT. Although the mainstream research continues along conventional lines, CIMMYT is increasing its efforts in "farm systems research", addressing questions such as crop management and agricultural economics. Greater emphasis is being placed on the development and dissemination of improved research procedures to national research programmes, as well as on the support of indigenous training programmes.

One of the more controversial issues the centre faces is the growing demand on both sides of the Atlantic for greater patent protection for plant breeders. Dr Borlaug, acting director of CIMMYT's wheat programme, has criticized the new legislative initiatives, arguing that they could make developing countries more vulnerable to exploitation by unscrupulous outside companies. But others at CIMMYT seem prepared to accept, if reluctantly that tighter patent rights could accelerate the dissemination of new agricultural technologies.

The changing economic dynamics of food production are producing their own tensions within CIMMYT. Until now the centre has been distributing its germplasm with no charge and virtually on request. But after recent incidents, the rules are being tightened up.

Some recent scientific developments are also being watched warily. For example, there is scepticism about the size of the potential contribution of recombinant DNA technology to the direct improvement of crop yields, and CIMMYT has no molecular biologists on its staff. "We think that Wall Street is being widely optimistic", says CIMMYT's director general, Dr Robert D. Havener, referring to the heavy investor demand for shares in the new genetic companies, and quoting Dr Borlaug's view that "it will be 50 years before there is any significant impact on complex plants coming out of genetic engineering".

At the same time, however, CIMMYT is strengthening its links with research scientists in developed countries so that they can exploit any major breakthrough. Meanwhile Dr Havener's principal concern is to ensure that political and economic pressures do not upset the arrangement under which centres such as CIMMYT operate with minimum outside interference and the maximum amount of flexibility.

David Dickson

This year the situation looks as if it will be even tighter. Pledges for donations made at last week's meetings totalled \$155 million, an increase of about 15 per cent over the currrent year. However, according to Mr Warren C. Baum, the present high inflation rates plus fluctuations in the exchange rates covering the currencies in which donations are made mean that real growth will be small.

The combination of financial stringency and structural changes in the international research environment stimulating various shifts in strategy. One has been to increase the emphasis on basic research either at the institutions themselves or through links with the international scientific community.

Complementary to this will be the efforts

to assist national research programmes. In the past, tensions have arisen when donors faced difficult choices over whether to allocate funds to a particular country's research effort or to the international institutions. At a meeting held earlier this year in Nairobi, Kenya, for example, representatives from several African countries expressed strongly their view that CGIAR as a group should be doing more to assist indigenous efforts in their region, a message which is now being acted upon.

Keen to maintain the minimum of bureaucracy, last week's meeting reacted equivocally to a suggestion from the review committee that a new committee be established to coordinate budget request and allocations, and the issue has been deferred.

David Dickson

#### **Animal committees**

SIR — Your article "Protection for laboratory animals?" (Nature 17 September, p.173) presents a rational and realistic appraisal of the present dilemma concerning the ethical use of animals in experimentation being faced by the scientific community, the animal welfare community and the legislator.

It was of significant interest to the Canadian Council on Animal Care (CCAC) that the article concluded with the suggestion of building into a new system of regulation the establishment of "a committee at every important centre at which animals are used that would be empowered to sanction (or not to sanction) proposed uses of laboratory animals". The CCAC, established as a committee of the Association of Universities and Colleges of Canada in 1968 "to work for the improvement in the care and use of animals on a Canada-wide basis", has had, as its cornerstone, the development of local committees on animal care, at every institution in the country using animals in research. It was, and is, the intention that this committee should act as the "conscience" of the institution in ensuring ethical animal use is practised.

We recognize that we are dealing with human beings whose abilities and motivation vary. Therefore, some committees are more effective than others. However, it is our objective to continue to monitor the activities of these committees, in order to ensure that the weaker ones are made strrong, and the stronger ones continue to be strengthened.

It is our opinion, and one based on experience, that a local committee comprising conscientious and strongly-motivated members can do more than legislation to ensure the ethical treatment of animals in research.

H.C. ROWSELL

Canadian Council on Animal Care, Ottawa, Ontario, Canada

#### On chemical war

SIR - As noted by David Dickson (Nature 1 October, p.327) and Philip Campbell (Nature 22 October, p.598) the last few months have seen a potentially dangerous escalation in chemical warfare. This escalation was symbolized by the Reagan Administration's decision in February to build a new nerve gas munitions plant in Arkansas, approved by the Senate at the end of May. US stockpiles of nerve gas already stand at well over 10,000 tons and while Warsaw Pact stockpiles certainly exist, their quantity is not known. France also has the weapons. The United States is known to have been pressing for a British contribution to its build-up. whether by stock-piling US weapons or other means, even though our government continues to endorse the policy which led to the disposal of the British stockpile in 1957 and the decision not to develop a replacement. Chemical warfare is prohibited by the Geneva protocol and customary international law.

A new chemical arms race in Europe would be an additional hazard over and above that already presented by nuclear weapons Furthermore, it would impose new military direction and priorities on research and development in the life sciences and

biotechnology. Currently, the Ministry of Defence is in contract with British universities to the tune of £5 million per annum. With bleak prospects in front of them, and the reduced level of funding by the research councils, university departments may be tempted to seek defence contracts and acquiesce to all that these entail.

We therefore call on scientific and technological colleagues not to participate in research associated with the development and production of chemical weapons; to urge the British government to forgo the production and stockpiling of chemical weapons in the United Kingdom; and to press the government

- (1) Withdraw its reservation of the right to retaliate in kind made by Britain when ratifying the 1925 Geneva Protocol.
- Resubmit the draft Chemical Weapons Convention tabled by Britain in 1976, revised to incorporate new proposals on verification, consultation, scope and confidence-building measures.
- (3) Promote specific negotiations on the withdrawal of chemical weapons from both sides of Europe.

A significant start in this direction has already been made, namely the support of 2,000 colleagues, including five Nobel laureates, in science, technology and medical faculties throughout Britain. Further support would be welcome.

#### Cancer monoclonals

SIR — The use of monoclonal antibodies in the treatment of cancer is at present being assessed and there is a section of the biomedical community, both scientific and administrative, that believes empirical clinical trials of monoclonal antibodies and toxin-antibody conjugates should be conducted immediately. I wish to present the arguments for a more orderly, scientific and cautious approach.

Three major points can be made in support of the latter case. The first is scientific: it is important to gather as much information as possible before clinical trials with monoclonal antibodies about the tissue distribution of the target antigen, chemical structure and so on. This is for two reasons. (1) The factors involved in either the success or failure of serotherapy cannot be assessed without this basic information. (2) The potential risks or benefits to the patient cannot be accurately measured - this is illustrated by two recent publications. The first reported the (unsuccessful) use of a monoclonal antibody against CALLA antigen in the serotherapy of acute lymphoblastic leukaemia1; the second that the CALLA antigen was not confined to lymphoid cells but was present on several other tissues, particularly in the kidney.2.

The second argument is ethical. The minimum right of a terminally ill cancer patient subjected to experimental therapy is that every effort has been made to assess the potential deleterious effects of the proposed therapy. Moreover, it can be argued that the

patient should also expect the potential benefits of the treatment to outweigh the

The final argument against empirical therapeutic trials of monoclonal antibodies before extensive preclinical testing is that of the relationship between the biomedical community and the general public. In the past, cancer patients and their families have had their expectations of more effective treatments for cancer raised unrealistically by the early optimistic reports of clinical trials with transfer factor, BCG and, more recently, interferon. The biomedical community would be well-advised to avoid a similar situation with monoclonal antibodies.

#### Room for Anon

SIR - I see that you have again used the word "culprit" in connection with users of the pseudonym Isadore Nabi (Nature 29 October, p.696).

Although I refrained before, I would now like to express my conviction that the use of a pen-name, in publishing a work of literature or science, is not of itself a culpable act. Indeed, the dangers would seem to be least in theoretical science, where such contributions can normally be judged on their intrinsic

As your readers may already be familiar with literary examples, such as that of the Brontes, I will recall a few examples from mathematics.

- (1) In statistics, "Student's test" is so known because it was originally published over the pen-name "Student". The author's true name is known to a few historians. Who says he did anything wrong?
- (2) In Annals of Mathematics (69, 247-251; 1959) we find a letter purporting to come from a mathematician long since dead, saying how glad he is to see his results discovered independently by the mathematicians of the present day. The letter convinces me of the present day author's standing both in mathematics and in the history of mathematics; and he chose an amusing way to make his point. Who says he did anything wrong?
- (3) The pen-name "N. Bourbaki" is used by a French mathematical syndicate, who have published some very useful books and gained a considerable reputation.
- (4) There is some tradition that serious mathematicians, if they write an occasional piece which is recreational or humorous, may shelter behind pen-names such as "H. Petard"

Your mathematical readers can find out which journals I help to edit. I would like to assure them that I shall treat pseudonymous contributions just like any other contributions - on their merits.

# Fast breeder reactors: can we learn from experience?

#### Otto Keck\*

INITIALLY, developing the fast breeder reactor (FBR) carried the promise of a virtually inexhaustible source of electricity at competitive cost. Now, three decades and substantial amounts of public expenditure later, we are not much closer to the fulfillment of that promise. Economic evaluations have consistently proved too optimistic. The commercial use of FBRs has been pushed back year after year. This experience gives little comfort to policymakers who have to decide about the next steps in FBR demonstration and commercialization.

Can we identify the sources of overoptimism and improve future policymaking? A close examination of the West German FBR programme, drawing on interviews with about 40 participants and the documents of government advisory bodies, shows a way to bring more realism into policy decisions1. The findings suggest that governments can redress the optimistic bias by requiring reactor manufacturers and utilities to make an increased contribution to the cost of the programme from their own funds. In particular, construction of a commercial-size demonstration plant should be made contingent on the utilities' willingness to finance it from their own funds. Does this proposal take due account of the potential long-term benefits to be expected from the FBR? An economic analysis of FBRs suggests that the answer is yes.

#### Precarious beginning

In West Germany, the development of the FBR began late compared with other countries. The principle of nuclear breeding was discovered in the 1940s, during the United States' effort to develop the atomic bomb. In 1951, a small American FBR produced the first nuclear electricity. By that time the Soviet Union and Great Britain had started on their own programmes.

The initiative for the West German programme came from the Karlsruhe nuclear research centre, a laboratory founded in 1956 with the objective of constructing and operating the research reactor FR2. Although industry contributed about half the construction costs of the reactor, the laboratory was basically

a government organization. When the design of the FR2 reactor was nearing completion, the Karlsruhe scientists looked for new tasks. New work was particularly urgent for the nearly 100 scientists and engineers in the technical division, who faced lay-off after completion of the FR2 reactor. The scientists' interest focused on the FBR and a project group was established in April 1960.

programme the benefits of Euratom money without taking away domestic control. Similar contracts were made in support of the French programme begun in the late 1950s, and of the Italian programme, for which the Euratom contract served as a primer. For the Karlsruhe team, the association implied authorization of an expenditure of DM 185 million (£16.6 million), extending the

The experience of the West German fast breeder reactor programme suggests ways of bringing more realism into governmental decisions on the development of new reactor types. In particular, reactor manufacturers and utilities should finance commercial-size demonstration plants from their own funds.

A preliminary programme for three vears costing DM 25 million (£2.1 million at 1960 exchange rates) was endorsed towards the end of 1960 by an advisory committee of the then Ministry for Atomic Energy. When presenting its plans, the Karlsruhe team referred to American and British forecasts that FBRs would assume a significant commercial role soon after 1970. But the advisory committee by implication rejected these forecasts when it stated explicitly that work on FBRs might be terminated after the preliminary three year programme. This cool reception came mainly from committee members with industrial backgrounds. Ministry officials were very much in favour of the project and the DM 25 million was only a fraction of what the ministry was prepared to spend for a rapid expansion of the Karlsruhe laboratory.

#### **Boost from Euratom**

The threat of possible termination did not worry the fledgeling Karlsruhe project for long. Coincident with the advisory committee's cool appraisal, the European Atomic Energy Community (Euratom) began to show interest in FBRs. The community had been founded in 1958 by Belgium, France, West Germany, Italy, Luxembourg and the Netherlands. It had little success in associating itself with national programmes for first-generation nuclear power plants (light-water reactors [LWRs] and gas-graphite reactors). To secure a useful function, Euratom committed its considerable funds to exotic technological niches, such as the organiccooled reactor, and to advanced designs, such as FBRs.

In 1963 the West German government signed an association contract with Euratom that gave the German FBR project up to 1967. Euratom was to contribute 40 per cent of these funds. This commitment made FBRs the main objective of the Karlsruhe laboratory and gave this reactor type the first priority in the West German reactor programme. In the period 1956–67 — before the first commercial orders for LWRs were placed — FBRs received more government support than any other reactor type.

This shift in priority was made without a fresh consideration of the economic need. For the Karlsruhe project, the Euratom association was a matter of survival. The Ministry for Atomic Energy was motivated mainly by the political aim to secure a fair return from West Germany's contributions to Euratom. In favour of this, it ignored the earlier cool appraisal of the FBR by its advisory committee.

#### Prototype design

In September 1964, the Karlsruhe team was shocked by the announcement by General Electric (US) that the company would offer a commercial FBR as early as 1974. The scientists felt that the West German programme must be pushed ahead as fast as possible to meet this competitive threat. They therefore proposed that work should start immediately on the detailed design of a 200–300 megawatt prototype plant two years earlier than previously planned.

At that time, the laboratory was working on two different versions of the FBR—one using sodium as coolant, the other steam. As a choice between the two seemed difficult, the scientists proposed designing and building one prototype plant of each type. The Ministry for Scientific Research, successor to the Ministry for Atomic Energy, awarded design contracts in November 1966 to two industrial consortia. It allocated DM 57.5 million

<sup>\*</sup>The author is affiliated with the University of Ulm, West Germany. This article was written while he was a German Kennedy Memorial Fellow at the Center for Science and International Affairs at Harvard University. It expresses his personal views and does not necessarily reflect the views of any of the organizations or individuals involved in the West German FBR programme.

(£5.1 million) for industrial work on the sodium-cooled prototype and DM 38.7 million (£3.5 million) for the steam-cooled prototype.

Apart from the threat of international competition, Karlsruhe's justification for accelerating the programme rested on estimates of electricity costs suggesting that, in the 1970s, FBRs would produce electricity for 15 per cent less than LWRs. The advisory committees did not discuss either argument explicitly. Implicitly the arguments were rejected when reactor manufacturers and utilities declined to make a contribution to the programme from their own funds, arguing that the economic use of FBRs was not foreseeable. Nevertheless, the ministry adopted the Karlsruhe estimates.

#### Termination of steam breeder

At the end of 1967, the industrial team working on the steam-cooled prototype discovered technical problems that prevented conversion of a small boiling-water reactor into a facility for testing FBR fuel elements. When plans for a 50 megawatt steam-cooled FBR in the United States were dropped in 1968, the ministry acknowledged that the ensuing lack of an information exchange with foreign programmes would increase the risks and costs of its own programme. It therefore decided in 1969 to abandon the steam-cooled FBR.

At first, the firms involved opposed termination. However, the ministry got their consent by asking them either to finance part of the further development costs or to agree to the termination. The firms preferred to spend their money on other projects.

#### **SNR-300**

The economic assessment of FBRs reached a turning point in West Germany when contracts for the 300 megawatt sodium-cooled prototype plant SNR-300 were negotiated. Quotes for construction cost were four times more than earlier estimates (excluding inflation). Fuel fabrication costs were quoted as about ten times the previous estimates for commercial FBRs. This ruled out any possibility of FBRs undercutting the electricity costs of LWRs as long as uranium from low-cost reserves was available.

A new economic assessment by an advisory committee concluded that global low-cost uranium reserves might be depleted around the year 2000, so that FBRs would not be needed before the 1990s. Probably two demonstration plants would have to be built after SNR-300 to bridge the gap to commercialization.

Postponement of the SNR-300 might have saved money by shortening this gap. However, changes in the schedule were difficult because the programme had acquired institutional momentum. A large proportion of the Karlsruhe laboratory as well of supplier firms was engaged on the FBR. If the teams were to be kept together, construction of the SNR-300 had to start within a relatively short time.

Construction began in 1973 with only two years delay against an earlier schedule. Belgium and the Netherlands participated in the project, each contributing a 15-per cent share. In 1973, the SNR-300 was

reckoned to cost DM 1,335 million (£205 million), excluding the plutonium fuel. Operation was planned to begin in 1978. Since then, costs have more than doubled (in constant prices). The latest estimate as of February 1981 gives a figure of DM 5,000 million (£1,050 million). Completion is now expected in 1986.

Nearly all the funding for the project has been and is being provided by the three governments. The utilities contribute about 8 per cent of the construction cost from their own funds. West German manufacturing firms finance 8 per cent of the related research and development they perform. The total cost of industrial research and development for the SNR-300, which is not included in the above figures, is estimated at DM 350 million (£75 million). Recently, the German utility participating in the project promised to contribute an additional DM 31 million both in 1981 and 1982, and the German reactor manufacturer pledged an amount of DM 10 million in each of these years. Even so, the firms' contributions to the overall project cost will still be less than 10 per cent. The governments also pay for all research and development performed in government laboratories. For West Germany, this implies an additional estimated expenditure of DM 950 million (£200 million) over the period 1973-82.

#### Lessons

The West German experience suggests that government laboratories and agencies are ill equipped for economic assessments. As they are remote from the commercial world, they may misread the information provided by industry or the technical literature. Organizational needs or political considerations often conflict with a realistic economic evaluation — and when they do, government organizations are tempted to opt for the former.

Reactor vendors and utilities have consistently made more realistic economic assessments than the governmental participants. Yet only at the outset did representatives of industry in the advisory committees volunteer their scepticism, and even that was prompted by the general dispute on the division of responsibilities between government laboratories and industry. Later, firms revealed their scepticism only when asked to contribute some of their own funds. Then they did so implicitly rather than explicitly, revealing it only to the extent that was necessary to defend the limits on their willingness to put up their own money.

As long as only government money is at stake, industrial participants in joint projects seem to have little incentive for a sober review and frank exposure of commercial and technical uncertainties. Criticizing economic assessments made by other organizations is unpleasant. Firms do not wish to exclude themselves from a government-financed programme by questioning the government's economic

West German FBR SNR-300 at Kalkar

justification. Indeed, they want to be part of the programme to know what is going on and to get some of the business.

These conclusions support the proposal<sup>2</sup> that the construction of commercial-size demonstration plants should be contingent on the willingness of utilities to finance the costs from their own funds. A nearcommercial framework should be applied that would require reactor manufacturers to back cost estimates by guarantees with respect to performance and cost, hence making them participate in the technical and commerical risks. Although there is a case for a greater role of government in the earlier phases of a development programme, at the demonstration stage government support should be restricted to the sharing of operating risks and to the financing of background work performed by government laboratories.

Whether demonstration plants are financed through taxes or utility bills, in the end the citizen will have to defray the cost. But the government is likely to get more realistic advice if it asks utilities whether they are prepared to charge the full cost to their customers' electricity bills.

#### Long-term benefits

Against this proposal it may be argued that the FBR may become an indispensable source of energy at some time in the future that is further away than the short-term calculations of utilities can accommodate. A demonstration plant has to be constructed soon, the argument goes, if we are to have the capability of constructing a larger number of FBRs ten to twenty years from now, when there may be a need to do so because of the depletion of uranium resources. A study by the Organisation for Economic Cooperation and Development (OECD) and the International Atomic Energy Agency (IAEA) estimates that at a cost up to \$130 per kilogramme there are about 5 million tonnes of uranium available in the non-communist world (reasonably assured and estimated additional resources). According to the growth projections for nuclear power by the International Nuclear Fuel Cycle Evaluation (INFCE), this may not satisfy demand beyond the year 2010.

But such calculations do not justify paying the penalties involved in constructing a FBR demonstration plant that is more expensive than what a utility would be willing to pay. Uranium prospecting and exploration have a very short history, and vast areas remain to be investigated. On the basis of indirect indications and of geological extrapolations, another study by OECD and IAEA has suggested that an additional 7-15 million tonnes of uranium deposits may be discovered with existing exploration techniques. These may carry nuclear power to the middle of the next century, if a modest growth of nuclear power is assumed.

Past projections of uranium supply and demand have proved an unreliable basis for

French FBR "Super-Phénix" at Creys Malville

policy decisions. Forecasts of future nuclear capacities have steadily been downrated, while estimates of uranium resources have continuously been increased. The lower of two growth projections for nuclear power published by INFCE appears unrealistic only one year later. We do not know how long this trend will continue. The nuclear industry in most countries is presently more concerned about its survival over the short term than about the long-term supply of uranium.

Given the large uncertainties in the longterm demand for uranium and the usual conservativism in resource estimates, there is no assurance that depletion of low-cost uranium resources will necessitate the use of FBRs within the next fifty years. Thus a prudent policy will take into account that depletion of uranium resources will not occur suddenly. As low-cost resources become scarce, the price of uranium may eventually rise to a level that may make the use of FBRs an economic proposition. Uranium resources are likely to be available in sufficient quantity for a transitional period until FBRs replace current types of nuclear reactors. Because of the long lead times of nuclear plant construction, the demand for uranium two to three decades ahead can be fairly easily assessed. The penalties for missing the right time for a transition to FBRs by a decade or two is rather small, as the cost of natural uranium accounts for less than 10 per cent of the total electricity costs in LWRs.

Once reprocessing is available on a larger scale, advanced core designs may become feasible for the LWR that greatly enhance its fuel efficiency. A study by Kraftwerk Union and the Karlsruhe laboratory, for example, proposed a core that uses five times less fuel than present designs. If such designs have lower electricity costs than FBRs, they may delay the need for FBR commercialization by decades.

Premature construction of an uneconomical FBR demonstration plant may also be advocated as an insurance against short-term interruptions of uranium supply. However, one FBR demonstration plant alone would make a negligible contribution, and construction of a series of uneconomical FBRs may provide the desired insurance at a much higher price than other options. A fully developed LWR fuel cycle is little affected by interruptions of two or three years. Longterm supply-contracts can greatly increase the reliability of the international uranium trade. If additional insurance is desired, stockpiling and preparations for emergency mining of low-grade domestic ores or for extracting uranium from seawater may be less expensive options than a series of uneconomical FBRs. Once the technical feasibility of advanced LWR cores is demonstrated and reprocessing is available on a larger scale, this technology will be a strategy, as virtually no insurance premium cost will have to be paid against the threat of a uranium shortage.

#### Economic uncertainties

The perspective that the SNR-300 throws on FBR electricity costs suggests that economic uncertainties are several and large. According to the latest estimate in February 1981, the SNR-300 costs about seven times more per kilowatt of net electric output than a commercial LWR, which was offened at that time at a price of about DM 2,550 (£540) per kilowatt (including owner's cost, but excluding the first core and the interest, inflation and taxes during construction). Scaling-up to sizes around 1,300 megawatt would reduce the cost per killowatt of the breeder by 40-60 per cent. But this would still imply FBR capital costs 2.7 to 4.3 times greater than LWR costs.

The firms constructing the SNR-300, nevertheless, argue that this plant may not be representative of future large FBRs. In particular they say that:

 The cost includes a good deal of research and development that will not have to be repeated for future plants.

- The SNR-300 design is sub-optimal with regard to cost, since design changes imposed by the licensing authorities had to be incorporated into a largely fixed plant concept.
- The supplier's engineering capacity was underutilized as it could not be deployed for other projects during the construction delays caused by the licensing procedure.

These arguments suggest that by extrapolating from the SNR-300 data we may overstate the construction cost of future large FBRs. But we do not know by how much. If engineering services are excluded from the SNR-300 cost estimate, my calculation still suggests FBR capital costs at least double those of the LWR. On the other hand, the costs of SNR-300 are bound to increase further before the plant is completed. As for the next few large FBRs, it is highly probable that most of the factors that have increased the cost of the SNR-300 will still apply, although perhaps to a lesser extent. These factors will become insignificant only if a series of nearly identical plants is constructed at the rate of about one a year.

The hopes of the FBR community now rest on the French 1,200 megawatt Super-Phénix, which costs about twice as much as a French LWR plant of the same size. FBR advocates expect that cost-saving design changes, a relaxation of safety requirements and series production will help reduce construction costs. However, experience with the LWR suggests that it is not certain that cost savings through learning and series production will be quickly achieved. LWR costs have increased dramatically over the past decade. The effects of learning and series production have been cancelled out by other factors such as changes in licensing requirements, increasing quality assurance and control, and schedule slippages.

Estimated fuel-cycle costs for the SNR-300 are so high that the plant would not be commercially competitive even with nil investment costs. According to a forecast in 1973 by the utilities owning and operating the plant, operating costs will be such that the net returns from the sale of electricity are just about enough to pay usual depreciation and interest on a capital investment of DM 100 million. This is less than the amount to be invested in the reactor core (fabrication and plutonium), which for the SNR-300 is paid for by the state, but in commercial operation would have to be financed as a fixed cost by the utilities.

Over the past few years, the cost estimates for the SNR-300 fuel-cycle have become even more unfavourable. Fuelfabrication costs have doubled in constant prices, while the fabrication costs of uranium fuel for LWRs have decreased in real terms. Thus the fuel-fabrication for the SNR-300 is now estimated to cost about thirty times more than for LWR fuel. The original estimate for reprocessing excluded the capital cost of the reprocessing facility.

It was based on the assumption that the fuel of the SNR-300 would be reprocessed in the West German WAK plant, but included no allowance for the construction cost of this facility or for the costs of its adaptation for FBR fuel. When exploring the possibility of reprocessing the SNR-300 fuel in foreign reprocessing facilities, the utility operating the SNR-300 received quotes that indicated much higher costs.

The dismally-high cost estimates for the SNR-300 are partly the result of the small scale on which the fuel cycle for this plant operates. But they also reflect soaring cost estimates for reprocessing of spent fuel and for fabrication of plutonium fuel in general. Because of its toxicity, plutonium fuel has to be fabricated in special plants. These plants can also fabricate plutonium fuel for LWRs. But at present they are still at a pilot or prototype scale.

Recprocessing facilities for LWR or advanced gas-cooled reactor (AGR) fuel can accommodate a few FBR fuel elements if these are reprocessed together with a larger number of LWR or AGR fuel elements. As long as the FBR capacity in operation is small compared with that of the LWRs or AGRs installed, this may be sufficient. Because FBR fuel has a higher plutonium content, generates more decay heat and contains more radioactive fission products than AGR or LWR fuel, the large-scale use of FBRs will, however, require either the modification of reprocessing facilities which were designed for AGR or LWR fuel or the construction of special facilities for FBR fuel.

Over the past decade, cost estimates for reprocessing of spent fuel and plutonium recycle have increased to a level that makes such operations commercially unattractive for LWRs at present uranium prices. The uncertainty persisting in these cost estimates is highlighted by the fact that present contracts with British and French reprocessors have basically a cost plus fixed-fee price. The cost of reprocessing will be known with some certainty only after the French and British have begun operating their large reprocessing facilities for oxide fuel now being constructed and when plutonium recycling is possible within a truly commercial framework.

Even then, however, some cost uncertainties will remain for the FBR fuelcycle, because its technology differs from the plutonium fuel-cycle for LWRs. One such difference concerns cooling time. If spent fuel is stored before reprocessing, its decay heat and radioactivity decreases, so that reprocessing can cost less. The West German reprocessing plant for LWR fuel planned for a site in Hessen is intended for fuel with a cooling time of seven years. Shorter cooling times are essential for FBRs, to make effective use of their notential to breed new fuel and to reduce the financial charges on the fuel bound up in the fuel cycle. It may be technically possible to achieve the desired short cooling time, but it is not yet known what

engineering efforts will be necessary and what impact this will have on reprocessing cost. There is a real possibility that these economic uncertainties may come out unfavourably and that a very large increase in the price of uranium may be required to make the electricity costs of the FBR competitive with those of the LWR. This would delay FBR commercialization by several decades or more. In such an event construction and operation of a demonstration plant would require a large subsidy while the demonstrated technology would become obsolete before a larger number of FBRs are constructed.

#### Time-risk trade-off

Construction of a large FBR demonstration plant in the next ten years or so thus reduces only one of several key uncertainties. It will tell us nothing about the future growth of nuclear power or the availability of uranium; and it decreases only a little the uncertainty about fuel fabrication and reprocessing costs, as these services then will still have to be operated on a small scale.

On the other hand, no matter whether a large FBR demonstration plant is constructed or not, every year that passes gives us more information on future demand for nuclear power and the availability of uranium. And if we wait until rising uranium prices make plutonium recycling a commercially viable operation for LWRs. we shall have a much better basis to assess the economics of the FBR fuel cycle. Yet this may take a very long time if long-term storage of spent fuel proves environmentally as acceptable as fuel reprocessing, and the near-term future of nuclear power is based on LWRs operated in a once-through mode without reprocessing. But the rewards of waiting will be great in terms of reduced economic uncertainties.

As the fuel-cycle facilities of the FBR build on technologies of the LWR fuel cycle, there is a clear case of a time-risk trade-off. Constructing an FBR demonstration plant in the next ten years or so will involve much higher technical and commercial risks than doing the same thing later. And the analysis of uranium supply and demand suggests that there is no commensurable benefit to the public from taking the high risk now rather than taking the much lower risk later. If an FBR demonstration plant has higher costs than utilities are willing to pay, and if risksharing by the government is not sufficient to bring the commercial risk down to a level acceptable to the utilities, subsidies from the taxpayers' purse would be used only to take an unnecessary risk. In such a situation, the short-term calculations of utilities are likely to lead to a decision that is consistent with the public's long-term interest.

#### NEWS AND VIEWS

### Secondary structure and evolution of ribosomal RNA

from Richard Brimacombe

THE DNA sequencing boom has had an enormous impact on many areas of biochemical research, and the ribosome field is no exception. A series of complete rDNA sequences is now available, and this has led not only to the construction of convincing secondary structure models for the corresponding rRNA molecules, but also to the realization that these secondary structures, as well as significant regions in the primary sequences, have been conserved to a remarkable extent throughout evolution.

The large ribosomal RNA molecules vary considerably in size from one organism to another. At the lower end of the scale are the small mammalian mitochondrial species, with rRNA molecules of 12S and 16S in the small and large subunits (approximately 950 and 1,550 nucleotides in length, respectively). In the middle are the ribosomes from bacteria, together with chloroplasts and other types of mitochondria, containing rRNA molecules of 16S and 23S ( $\sim 1,550$  and 3,000 nucleotides) and at the upper end of the scale are the eukaryotic cytoplasmic ribosomes with rRNA molecules of 18S and 26-28S ( $\sim 1,800$  and up to 4,000nucleotides, respectively).

#### Sequencing

The first rDNA sequence, that of 16S rDNA from Escherichia coli, was completed only three years ago1. Now the list of available sequences includes the 23S rDNA from E. coli<sup>2</sup>, the 16S and 23S rDNA from maize chloroplasts<sup>3</sup>, the 12S and 16S rDNA from human mitochondria4 and mouse mitochondria<sup>5</sup>, the 15S rDNA from yeast mitochondria6, and the 18S rDNA from yeast<sup>7</sup> and Xenopus laevis<sup>8</sup>. Further sequences were reported at the recent EMBO Symposium on Ribosomes\*, including the 23S rDNA from Bacillus stearothermophilus (Noller, Santa Cruz), 15S rDNA from Aspergillus nidulans mitochondria (Köchel, Göttingen), and the 26S rDNA from yeast (Planta, Amsterdam); the 28S rDNA from Xenopus is well on the way to completion (Gerbi, Providence). Partial sequences from a host of other organisms have also been described, and in addition the complete 16S molecule from Proteus vulgaris has been

worked out by direct RNA sequencing methods9. In short, we now have examples of ribosomal RNA or DNA sequences from all the principal categories mentioned above, with the notable omission of an archaebacterial map.

#### Secondary structure

In order to get from primary sequence to structure, sequence secondary comparisons have been combined with various experimental approaches based on data derived from E. coli 16S and 23S rRNA. Three groups, in California, Strasbourg and Berlin, have been principally concerned in these studies, and each group has independently constructed models for the secondary structure of the ribosomal RNA from both subunits. The experimental approaches have been (1) the analysis of sites of chemical modification by single-strand specific reagents (California), (2) the analysis of sites of clipping by single- or double-strand specific ribonucleases (Strasbourg), and (3) the isolation and analysis of short basepaired fragments of the RNA, together with the determination of sites of intra-RNA cross-linking (Berlin).

The various possible secondary structural features suggested by these experimental data can then be tested by sequence comparisons, in order to derive the correct structure. This sequence comparison approach, which was successfully applied some time ago to the case of 5S rRNA by Fox and Woese<sup>10</sup>, is in essence very simple. If two very similar but not identical sequences from different organisms are compared, then a base change in one strand of a putative doublehelical region must be compensated by a complementary base change in the other strand. Thus, an A-U base pair in one species could become a G-C pair at the corresponding positions in the second species, and so on. If the base changes between the sequences do not compensate each other in this way, then the implication is that the proposed element of secondary structure is incorrect. The secondary structure models for 16S and 23S rRNA have been successively refined by this approach, the latest versions (for the small subunit) being by Noller and Woese11, Stiegler et al. 12 and Zwieb et al. 13, for the the large subunit, the Berlin and

Strasbourg groups recently published structures almost simultaneously14.15, whereas the model from the Californian group is still in the final stages of preparation.

The secondary structure models for both subunits are in about 80 per cent agreement with one another. Although there are still some important differences, the main features, that is, the 'long-range interactions' between RNA segments widely separated in the primary sequence and which serve to divide the molecules into well defined structural domains, are firmly established. It is also clear that all molecules in the same size class (16S or 23S rRNA) can be arranged in almost identical secondary structures, and the extent of primary sequence homology within this class is very high; maize chloroplast rRNA is, for example, 70 per cent homologous with E. coli rRNA, and if the two 23S molecules from these species are compared, then over 450 compensating base changes can be found between the proposed secondary structures.

#### Size difference

More exciting, however, is the finding that the structural comparisons can be continued outside the 16S and 23S rRNA size classes both to smaller and to larger rRNAs. The Berlin and Strasbourg publications cited above show that the small mammalian mitochondrial rRNA molecules (12S and 16S) contain many elements of secondary structure precisely equivalent to their 16S and 23S counterparts. Reduction in size is achieved by simple amputation of secondary structural loops, or by erosion of a whole domain. Recognition and location of secondary structural features is made easier by searching for stretches of conserved primary sequence, which tend to be - but are by no means exclusively - in singlestranded regions. There are, however, some interesting anomalies, where apparently significant stretches of homology have 'leap-frogged' each other in the different sequences. Precisely the same situation pertains if one makes a comparison with the longer eukaryotic

Richard Brimacombe is in the Max-Planckthree groups, respectively. In the case of Institut für Molekulare Genetik, Berlin-

Dahlem.

cytoplasmic rRNA molecules (see also ref. 16). The same secondary structural features are conserved, and the extra sequences in the eukaryotic molecules are accomodated in precisely those regions which are shortened in the case of the small mitochondrial species. Again, there is striking conservation of primary sequence in both single- and double-stranded regions. The secondary structure comparisons also confirm the suggestions (based on primary sequence homology) that eukaryotic 5.8S rRNA is equivalent to the 5' end of prokaryotic 23S rRNA17, and that the 4.5S rRNA from chloroplasts is correspondingly equivalent to the 3'end of the bacterial 23S rRNA18.

One should not be too surprised by these findings; after all, both tRNA and 5S rRNA have been highly conserved throughout evolution. What is important is that the extension of the conservation to the large ribosomal RNA molecules of all classes has now been clearly demonstrated, and that this conservation will per se be a powerful tool for testing the validity of any new structural or functional proposals in the future.

glaciology is whether or not the West Antarctic Ice Sheet (WAIS), as well as the East Antarctic Ice Sheet, is stable. It is suspected that it is inherently unstable because its base is far below sea level for most of its area. A related question is whether the expected increase in atmospheric CO, and the climatic warming it may produce will propel the ice sheet to its destruction.

#### Stability

The symposium opened with sessions addressed to the problem of ice sheet stability. Because most of the ice of the WAIS is drained through ice streams, the latter and their relationship to stability received much attention. One way to find out whether the WAIS is growing, is slowly disintegrating or is in a steady state is to see if the grounding lines where they meet ice shelves are stationary. British Antarctic Survey (BAS) scientists reported the first ever measurement of the position of an ice stream (Rutford Ice Stream) grounding line made with sufficient precision to determine within the next few years if it is stationary or not. We should not have to wait too long to learn whether the WAIS over the next century is benign.

Ohio State and Grenoble Universities glaciologists used indirect evidence of the volume of air in ice from the Byrd Station bore hole to conclude that the WAIS has been rather stable during past major climate and glacial changes. It has been stressed by University of Maine researchers that the Pine Island Glacier is where the WAIS may collapse but studies by BAS glaciologists have found no evidence of instability - although their findings cannot rule out its existence. The last 100 km of the Pine Island Glacier were found to be afloat and to be essentially a onedimensional ice shelf. The existence of this ice shelf separates the calving front from the grounding line and probably increases

#### Carbon dioxide

stability.

Whether a carbon dioxide build-up will make the Antarctic ice more or less stable is not certain. One definite piece of evidence was reported by University of Bern geochemists. The data, reconfirming their earlier work as well as that obtained at Grenoble, show that the CO<sub>2</sub> content of the atmosphere during the last ice age was lower than it is now. The measurements were made on entrapped air within ice cores brought up from deep within the ice sheets but whether the low CO, content is the cause, or is the effect, of an ice age is still anyone's guess. If a low CO, content and a large ice volume go hand-in-hand, then it is possible that a high CO, level could cause at least the West Antarctic ice to decrease in volume. A process that is likely to produce

#### On Antarctic glaciology: Ice sheets. .

from J. Weertman

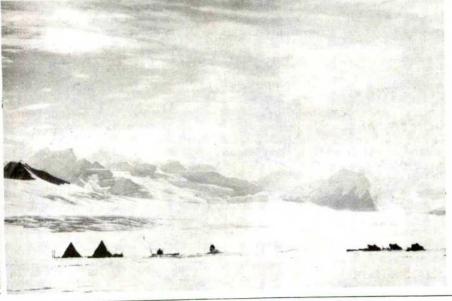

An international symposium on Antarctic glaciology\* was held this autumn at Ohio State University. It was only the third meeting on this topic in over twenty years and it might be supposed that progress in this field moves at the proverbial speed of a creeping glacier. Actually, the pace of research has accelerated greatly in keeping, perhaps, with the recent discovery that the major glaciers in Antarctica, namely the great ice streams, move with impressive velocities.

Results were reported from research projects carried out in virtually all parts of the Antarctic continent, in oceanic islands

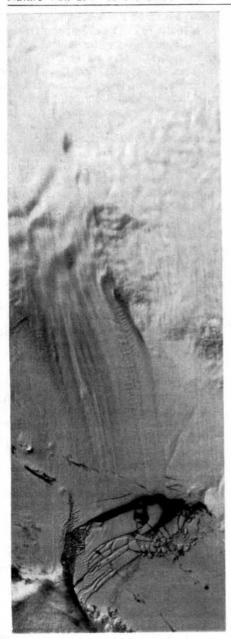

near the continent, and on the sea ice that surrounds it. The topography of the Antarctic ice sheets has been partially surveyed from satellites, with an elevation error of about 1.5 m, and the ice sheets have been probed by deep drilling (most recently by a 900 m core hole at Dome C in East Antarctica), by seismic sounding and by radar sounding. Data were obtained that describe in an increasingly quantitative manner the present ice mass and some of its past history and offer clues to its future behaviour.

The most interesting problem that remains to be solved in Antarctic

Field camp on the Rutford Ice Stream with the Vinson Massif in the background.

©1981 Macmillan Journals Ltd

A NASA Landsat picture of the Pine Island Glacier. At the top of the picture the glacier ice is more than 2,000 metres thick but this falls to 500 metres where icebergs are calving off into Pine Island Bay at the bottom of the picture.

a reduction in ice volume is an increase in the rate of calving which would eventually lead to the destruction of the ice shelves and of the ice sheet they fringe.

#### Warming effect

The calving process is not well understood but a big advance was reported by University of Maine scientists who used rather detailed computer modelling calculations to study the process. We are still a long way though from predicting what would be the effect of, say, a 1°C warming produced by a CO<sub>2</sub> increase on the rate at which icebergs are created in Antarctica.

J. Weertman is in Northwestern University, Illinois.

SINCE THE 1960s, when it was recognized that a chronological history of the composition of the atmosphere is contained in the Antarctic ice sheets, ice drilling has featured strongly in most national programmes. Analysis of ice cores is now making it possible to reconstruct variations in past climate, global volcanic activity and atmospheric pollution. The symposium provided an opportunity to review progress in these areas.

Particularly dramatic has been the evidence from deep ice cores of changes associated with the transition from the Wisconsin (Würm) glaciation to the Holocene. Lorius (Laboratoire de Glaciologie, Grenoble) discussed new data from the 905 m Dome C core which support earlier reports by Thompson (Institute of Polar Studies, Ohio State University) from this and the Byrd core that the number of microparticles increased by a factor of eight, relative to Holocene values, during the last glaciation.

But to what extent is the inverse relationship between increased particle load and temperature causal? Lorius Glaciologie, Grenoble) has detected the influence on sulphate levels of several major volcanic events in both recent firn and in ancient ice back to 30,000 years BP. The input of sulphate from volcanic sources is only significant during the three to four years following an eruption. Such studies will provide an accurate record of volcanic activity over periods of tens of thousands of years and should also provide a powerful method for dating ice cores.

However, there is still a substantial input of sulphate in volcanically quiet periods which cannot be accounted for by input of marine salts. Delmas supports the idea that it originates in part from the oxidation of biogenic gaseous sulphur compounds, such as DMS, at the ocean surface. The aerosol may then be transported to the polar plateau through the upper troposphere. On the other hand Herron (State University of New York, Buffalo) has found clear seasonal variations of sulphate with summer maxima which do not correlate with marine chloride. Thus he believes a non-marine gaseous sulphur compound is the most likely source, with

#### . . . and ice cores

from David A. Peel

argues that a global increase in arid areas during the last glaciation combined with a fifty per cent increase in wind speed associated with a strengthened meridional circulation would be sufficient to account for the enhanced microparticle load. In the sections of core analysed by his team he could find no evidence for increased volcanic activity in the glacial period either by examination of the larger particles, or in the levels of gas-derived sulphate. However, Thompson has clearly identified bands of large (60-80 µm) volcanic glass fragments in other segments of the same core and found they occurred with greater frequency in the Wisconsin. Clearly, a means must now be sought to distinguish whether dust in the smaller and more abundant size ranges is volcanic or continental in origin. Millar (Scott Polar Research Institute, Cambridge) gave evidence that radio-echo sounding can detect the acid layers associated with volcanism and provides a means for deducing broad changes in the level of volcanic activity over periods of tens of thousands of years. This type of study could, in the future, rapidly extend knowledge previously based on the much slower analysis of ice cores.

The major impurity in Antarctic ice is sulphate yet the mechanism by which it reaches the Antarctic ice sheet is largely unexplained. Application of new methods has allowed much more detailed sampling from a wider area than before. In the Dome C ice core Delmas (Laboratoire de photooxidation of the gaseous precursor

photooxidation of the gaseous precursor playing a significant role. A clear inverse relationship between snow accumulation rate and sulphate concentration at sites in both Greenland and Antarctica further indicated dilution by snowfall of aerosol derived from a gaseous precursor in the upper troposphere or lower stratosphere.

#### Nitrates

Nitrates in snow are presenting greater difficulties. Zeller has made extensive measurements on 100 m cores and shallow pits at South Pole and Vostok station which support his earlier evidence that much of the NO<sub>1</sub>-N in Antarctic snow is derived by auroral fixation of NO, and follows an 11 year cycle in solar activity. Elevated NO<sub>1</sub>-N levels coincided with years of solar flare activity peaks which are associated with high auroral activity. Pronounced seasonal variations with maxima in winter months could be due to summer photochemical destruction of much of the NO. The broad, longer term changes at the South Pole and Vostok were similar with prolonged, low NO3-N concentrations at the time of the Maunder minimum (1617-1710).

In contrast, Herron, who also included NO<sub>3</sub> measurements from the South Pole in a detailed investigation of the anion content of snow, although agreeing with the mean NO<sub>3</sub> values reported by Zeller,

David A. Peel is a member of the British Antarctic Survey (Natural Environment Research Council), Cambridge.

observed much less variance in concentration even with a greater sampling frequency and could not detect any deviation during the period of the Maunder minimum or any of the spikes which Zeller attributes to solar flare or supernovae events. Moreover, he detected a seasonal variation with summer maxima in parallel with variations in sulphate. Delmas also found that nitrate concentrations in the

Dome C core have been relatively constant over the last 30,000 years. To complicate the picture even further, in a detailed profile at James Ross Island he found virtually no seasonal variability. In view of the potentially great value in using nitrate to trace past solar fluctuations the conference agreed that high priority should be given to resolving these seemingly incompatible data series.

#### A virus associated with human adult T-cell leukaemia

from Robin Weiss

RECENT virological, serological and epidemiological evidence strongly indicates that a newly discovered retrovirus is the aetiological agent of certain types of adult T-cell lymphoma/leukaemia. The virological evidence first came from R.C. Gallo's laboratory at the US National Cancer Instititute1 where the retrovirus was isolated from a T-lymphoma cell line established in culture from a patient with mycosis fungoides. In this issue of Nature Poiesz et al. (see p.268) report the isolation of a similar virus from a patient with Sézary syndrome, while Kalyanaraman et al. (see p.271) show that the two patients' sera (and that of a patient's spouse) contain antibodies which specifically react with the major core protein of the virus.

Mycosis fungoides and Sézary syndrome are clinical variants of cutaneous T-cell lymphoma and leukaemia, respectively, that occur as rare diseases in adults<sup>2</sup>. The retrovirus particles produced by these tumours are not evident until the tumour cells are grown in culture, although a second biopsy from the first patient released virus within 24 h of its being placed in culture. Until 5 years ago it was very difficult to maintain normal or malignant T cells in culture; however, a specific T-cell growth factor (TCGF) discovered in Gallo's laboratory3 enables T cells to proliferate in vitro for long periods, and this aided the detection of the virus.

#### Properties of HTLV

The virus, called HTLV (for human T-lymphoma virus), seems to be quite distinct from the numerous types of animal retroviruses previously described. By its morphology and the molecular weight of virion proteins, HTLV most closely resembles bovine leukosis virus, which causes lymphoma in cattle. However, the human and bovine viruses seem unrelated antigenically or by nucleic acid homology.

Following Gallo's report of virus production from T-lymphoma cultures, an

independent virus isolate has been made in Japan<sup>4</sup> from a previously established malignant T-cell line5. Now Miyoshi and his colleagues, in a paper shortly to be published in Nature, claim that cocultivation of the T-leukaemia cells with umbilical cord leukocytes leads to the transformation of the cord leukocytes into a TCGF-independent cell line producing retrovirus particles. This is the first experimental evidence for infectious transmission and cell transformation with HTLV.

#### Origin of HTLV

Gallo's laboratory has not succeeded in transforming animal or human cell lines with HTLV, but they have not tested cord lymphocytes nor used co-cultivation. They think that T lymphocytes from some relatives of patients may support the replication of HTLV. At a recent meeting of the Leukaemia Research Fund in England, Gallo reported individual isolates of HTLV from four cutaneous T-lymphoma patients. From one patient an Epstein-Barr virus-positive B-lymphoblast line was also developed: this line was negative for HTLV, suggesting that HTLV is specifically associated with the tumour cells. Serological tests on some hundreds of American normal individuals or patients with diseases other than T-cell malignancies have been negative for antibodies reacting with the HTLV p24 core protein. By no means all T-cell leukaemia patients are positive either; the virus appears to be associated with a particularly malignant, fast growing form of tumour. Gallo thinks that all four patients (three black and one white) from whom HTLV has been isolated have Caribbean connections and that the virus may be more commonly found there.

The most striking epidemiological studies, however, come from Japan. There is a relatively high incidence of patients in major Japanese cities presenting an aggressive form of adult T-cell leukaemia. Uchiyama et al.6 noted that 13 out of 16 patients with this form of disease were born and grew up on the west coast of Kyushu, Japan's extreme south-west island. A more recent study<sup>7</sup> of 272 T-cell leukaemia cases shows a remarkable clustering of places of birth, in the Kagoshima and Nagasaki prefectures of Kyushu. Sera from all the leukaemia patients tested and from 25% of healthy adults sampled react positively with Miyoshi's virus isolate4. Through Yohei Ito, Gallo has found that Japanese sera also recognize his viral p24 antigen.

Several viruses are implicated as aetiological factors in human malignancies; Epstein-Barr virus in Burkitt's lymphoma and nasopharyngeal carcinoma are the classic examples. The association of hepatitis B virus infection with liver cancer has become apparent although it is curious that this virus does not even merit passing mention in two major compendia on tumour viruses published as recently as 19808.9. Cancer of the uterine cervix may well have an infectious agent as an aetiological factor, for which herpes simplex and papilloma viruses are under suspicion. During the 1970s claims for isolating human retroviruses have perhaps been made too frequently and prematurely. While some proved to be animal viruses acquired during laboratory procedures, others remain enigmatic, such as the viruslike particles seen in full-term placentae<sup>10</sup>. Four laboratories — Bentvelzen's in Holland, Gallo's at the National Institutes of Health, Kaplan's at Stanford and Kirsten's in Chicago — have independently isolated from human tissues retroviruses related to those of gibbons and baboons. These isolates are generally dismissed as laboratory contaminations. I am reluctant to disclaim their human provenance so lightly, although admittedly human antibodies which were thought to bind to these viruses specifically now appear to recognize heterophile carbohydrate groups present on the viral glycoproteins<sup>11,12</sup>.

#### Role in malignancy

The striking features of the T-cell leukaemia virus are its unique biochemical properties, its association with a particular subset of T-cell lymphoma/leukaemias and the geographical clustering of that disease in Japan. The discovery of this new virus followed the successful development of culture methods for T cells. The epidemiological findings would not have been possible without careful classification of leukaemias into B- and T-cell classes and further subclasses. A fascinating and important story is unfolding on the viral aetiology of a human malignancy.

#### Progress on accretion disks

from J. Craig Wheeler

ASTROPHYSICISTS are wrestling with the study of a new kind of star, the flat twodimensional configurations known as accretion disks. Accretion disks exist in a variety of contexts where mass is deposited to swirl around a compact star such as a white dwarf or a neutron star. They are suspected to play a part in more exotic situations, like active galactic nuclei and quasars, where the central object is imagined to be a supermassive black hole. The study of these objects is still in its infancy, analogous to the early days of Eddington when stars were modelled using elementary scaling laws without benefit of knowledge of the nuclear processes which powered the stars. Similarly, the power by which accretion disks radiate is suspected to come from a form of turbulent friction, the basic physics of which is known only at the crudest level. Most of the current literature on accretion disks is couched in terms of parametrized scaling laws which avoid direct confrontation with our most basic levels of ignorance. The letter by Abramowicz in this issue of Nature (p.235) adds needed rigor to our understanding of the structure and evolution of accretion disks while exploring an instability in the disk structure which has plagued earlier models.

Accretion disks were first defined as astronomical entities in the context of cataclysmic variables. In these systems, which include novae, matter from the outer layers of an ordinary star is attracted by the gravitational influence of a nearby orbiting white dwarf star. The matter lost from the ordinary star cannot strike the surface of the tiny white dwarf directly, but settles into nearly keplerian orbit. The viscosity in the disk causes heating and radiation and a slow spiralling of the material onto the surface of the white dwarf.

The rapid advances made in X-ray astronomy in the past decade have identified similar systems in which the accretion disk whirls about a neutron star rather than a white dwarf. The inner reaches of the accretion disk extended deeply into the gravitational potential of the neutron star where very rapid motion is the rule. The energy released by friction and the actual raining of the material from the disk onto the surface of the neutron star is so great that the radiation comes off in a powerful flood of X rays. In at least one binary system explored by X-ray astronomers, Cygnus X-1, the object in the centre of the accretion disk is thought by many to be a black hole, the ultimate form of collapsed matter.

Complete understanding of the out-

bursts of cataclysmic variables and X-ray production by neutron stars demands knowledge of the associated accretion disks. Through such study may also come deeper insight into phenomena such as active galaxies where matter from millions of stars may gather around a gigantic black hole in the galactic centre.

Previous work has shown that portions of accretion disks are unstable, leading to the clumping of matter into rings or bloating into a fat hot doughnut, in contradiction to assumptions that the disks are geometrically thin. However, there is no observational evidence that accretion disks do, in fact, suffer from these instabilities. Abramowicz argues that these instabilities may not occur in reality, and he shows that added gravitational effects due to general relativity alter the potential compared with the standard newtonian case in such a way that the instabilities are removed.

Ironically, this work may have most direct application in the case of accretion disks around supermassive black holes where observational confirmation of the basic picture is weakest. Abramowicz argues that the major inner radiating portions of such a supermassive disk will be stabilized in this case. The relativistic effects of which he speaks should also apply to putative stellar mass black holes, as in the case of Cygnus X-1, but this system is know to undergo some transitions in its radiative properties which have been discussed in terms of disk instabilities. For systems with white dwarfs and neutron stars the surface of the star or the presence of a surrounding magnetosphere may dominate the inner portions of the disk and overwhelm the relativistic effects described by Abramowicz. Even in the case of supermassive black holes there is speculation that the inner region consists of a nearly spherical, differentially rotating configuration, so that the basic assumptions underlying a thin disk analysis do not apply.

This discussion serves to illustrate the complexity of the phenomena known collectively as accretion disks. Progress towards understanding them will involve defining and solving restricted problems just as was done, and continues to be done, for ordinary spherical stars. The work by Abramowicz gives a new valuable example of the care which must be taken before reaching definitive conclusions regarding accretion disks.

#### Geomechanics in the laboratory

from Neville G.W. Cook

THE increasing use of the ground beneath us, whether in mining activities, underground construction or in the disposal of toxic wastes, requires, as does an understanding of earthquakes, a much deeper knowledge of the behaviour and properties of rocks than has sufficed in the past. To understand the behaviour and properties of rock masses, in situ tests are possible but they are costly and time consuming<sup>1-3</sup>. As became clear at a recent conference (see Geophysical Research Letters 8, 1981 for the proceedings) there is a need for laboratory tests on a scale of the same order as that of the in situ tests, both to avoid many of the restrictions of in situ tests and to bridge the gap between them and usual laboratory tests.

The most common kind of laboratory test on rock is the 'triaxial' test first introduced in 1911 (see ref.4). Right circular cylinders of rock, usually a few centimetres in diameter and several times greater in length, are subjected to axial compression between the platens of a mechanical press and an equal radial compression, applied through an impermeable membrane by a confining fluid pressure.

There are fundamental differences in the problems faced by laboratory testing in increasing deformation leads to decreasing

engineering mechanics and in geomechanics. In engineering mechanics, man-made materials are generally used and laboratory specimens can be expected to have similar properties to those of structural members made of the same material. Such materials are relatively simple in composition and structure compared with the composition and structure of most rocks. Again, laboratory test specimens of manmade materials are usually within an order of magnitude of the size of structural members whereas the dimensions of excavations and geological features can be many orders of magnitude greater than those of the rock specimens.

A further problem is that systems comprising conventional, soft testing machines and specimens of brittle rock become unstable at or beyond the peak of the stress strain curve<sup>5</sup>. Until the advent of stiff or servo-controlled testing machines, it was impossible to study the 'worksoftening' deformation of rock, where increasing deformation leads to decreasing

J. Craig Wheeler is in the Department of Astronomy, University of Texas at Austin.

Neville G.W. Cook is Professor of Mining Engineering, Department of Materials Science Mineral Engineering, University of California, Berkeley.

0028-0836/81/470213-02\$01.00

resistance to deformation. Stable, worksoftening deformation is of great importance in many practical problems, such as the stability of underground excavations and aseismic movement along faults. A final difference is that it is possible to subject specimens of man-made materials to loads similar to those they will experience in use, while small laboratory tests cannot reproduce the effects of stress concentrations in metres to kilometres in a rock mass subjected to a poorly understood state of stress.

Despite these limitations, the triaxial laboratory test has been of immense value in providing scientists and engineers with an understanding of the behaviour and properties of rock. As examples can be cited the transition from brittle to ductile behaviour as a function of confining stress and temperature, the effects of fluid pressure, and the phenomena of dilatation and brittle cracking in compression<sup>6,7</sup>.

The behaviour and properties of most rock masses in situ differ from those measured in conventional laboratory tests on specimens of the same rock. The reasons for these differences are not well understood but it is likely8,9 that size is one

of the factors involved. There are likely to be many others, such as variations in geological composition and structure, on all scales.

At present, three large-scale laboratory test facilities using specimens of rock with dimensions of the order of a metre are in use in the United States. The three facilities have each been designed for a specific purpose - the Lawrence Berkeley Laboratory triaxial apparatus for testing the mechanical and hydraulic properties of jointed rock at low stresses<sup>10</sup>, the US Geological Survey's biaxial frame for testing simulated faults in large blocks for rock<sup>11</sup>, and the Terra Tek Drilling Research Laboratory.

The proceedings of the workshop made it clear that large-scale laboratory testing is likely to be much more costly than is conventional laboratory testing, but such a facility will answer fundamental questions in rock mechanics. Comprehensive measurements of phenomena occurring inside a rock specimen, such as the location of sources of acoustic emission and fracture initiation and propagation, could be made under a wide range of controlled conditions of stress or strain, pore fluid pressure and temperature.

It was pointed out that the simplicity of the triaxial test is deceptive; it, in fact, involves homogeneous axial strain and homogeneous radial stresses. A large-scale triaxial high pressure and temperature cell may be excessively costly and potentially hazardous. A successful large-scale laboratory testing facility is likely to have to be different in concept and design from a conventional triaxial cell.

#### Morphological stasis and developmental constraint: real problems for neo-Darwinism

from Peter G. Williamson

A recent News and Views article1 commented on a paper of mine2 which summarized a morphometric analysis of mollusc lineages from a Cenozoic sequence in North Kenya. I had made three key points: (1) all lineages exhibit morphological stasis for very long periods of time (3-5 Myr), (2) evolutionary change in each lineage is concentrated in relatively rapid speciation events (occurring over 5,000 to 50,000 years) and (3) the speciation events are accompanied by pronounced developmental instability in the transitional populations.

The first two points indicate that these lineages conform to the 'punctuated equilibrium' model for evolutionary change and the third is significant because the unusually complete Turkana Basin sequence offers the first fine-scale palaeontological documentation of the speciation process.

The News and Views article considers only the second of these three points, making the uncontested observation that geneticists have succeeded in producing significant phenotypic changes in many populations over periods considerably shorter than those required for speciation events documented in the Turkana Başin mollusc sequence. The question of rapidity of speciation events is addressed but no attention is paid to the problems either of long-term morphological stasis or of developmental instability during speciation. Such comments are the standard but largely tangential criticisms advanced by many evolutionists against the punctuational model. The possibility of rapid change is freely admitted, but the significance of stasis, and the implications developmental constraint for evolutionary process, are ignored. Since the critique (and others recently published)3-5 seem to miss the most important issues raised by punctuated equilibrium theory in general, and my own work in particular, some comments seem in

As Gould and Eldredge<sup>6</sup> and many others have repeatedly pointed out, punctuated equilibrium is a theory about the deployment of speciation in time. It holds that many, perhaps most, metazoan fossil sequences show a characteristic pattern of morphological change through time: new species enter the record abruptly (in geological time), and persist with little significant change until extinction. Significant evolutionary change is, therefore, concentrated at speciation events.

For reasons that elude many of us, punctuated equilibrium, a theory of evolutionary tempo, has been conflated

Peter G. Williamson is Assistant Professor of Geology at Harvard University.

with Goldschmidtian macromutation, a theory of evolutionary mode. Thus, in the critique of my paper, I am lumped with Goldschmidt (and Cuvier of all people) as disciples of some peculiar (and nonexistent) non-Darwinian evolutionary school. But punctuated equilibrium is compatible with much current neo-Darwinian thought. Eldredge and Gould7, in their original formulation, relied upon the most orthodox version of Mayr's theory of allopatric speciation via peripheral isolates to account for the 'punctuational' pattern of morphological change in the fossil record. They considered the abrupt appearance of new species and their subsequent stasis, as well as the lack of intermediates between such stable lineages, to be compatible with (indeed, to flow from) Mayr's model. Mechanisms for rapid speciation that have been proposed subsequently (for example, the various models for 'chromosomal' speciation) are compatible with but not required by punctuated equilibrium, a theory of evolutionary tempo that is agnostic about modes of speciation, so long as they yield (as most standard models of speciation do) the punctuational pattern when translated into geological time.

It is not news to punctuationists that population geneticists can produce rapid phenotypic shifts in artificial selection regimes within a few generations -

punctuationists and conventional neo-Darwinians are in complete agreement on this point. Why, then, are many punctuationists increasingly unhappy with conventional neo-Darwinian accounts of fundamental evolutionary process?

The principal problem is morphological stasis. A theory is only as good as its predictions, and conventional neo-Darwinism, which claims to be a comprehensive explanation of evolutionary process, has failed to predict the widespread long-term morphological stasis now recognized as one of the most striking aspects of the fossil record. The long-term morphological stasis noted by punctuationists in the fossil record is clearly mirrored by the relative morphological uniformity of most widely distributed modern species. As Ernst Mayr, the foremost student of geographical variation has writtens: '...it would . . . seem important to stress the basic uniformity of most continuously distributed species . . . The fact that (every taxonomist)...can identify individuals of a species . . . regardless of where in the range of the species they come from is further illustration of this phenomenon'. In a belated attempt to address the problem of morphological stasis, neo-Darwinists have invoked 'stabilising selection' (for example, Stebbins and Ayala<sup>5</sup>). But the wide range of environments presently exploited by extensively distributed but morphologically uniform modern species, and the long-term morphological stasis (up to 17 Myr) exhibited by many fossil lineages in fluctuating environments, strongly argues against the idea that simple stabilising selection is an adequate explanation for the phenomenon of morphological stasis. Accordingly, Mayr explicitly invokes some form of developmental homeostasis, rather than stabilising selection, to explain the rangewide morphological stability of most modern species.

In the original formulation of punctuated equilibrium theory, it was suggested that temporal stasis, like the geographic stability noted by Mayr, was largely the result of some form of developmental constraint or homeostasis. In the absence of a comprehensive genetics of development, the mechanism for such homeostasis is obscure. But if some form of developmental homeostasis is at the root of morphological stasis, speciation must, by definition, involve the dismantling of homeostatic mechanisms pre-existing in the parental stock. The principal argument In my paper is that when speciation events occur in the Turkana Basin mollusc sequence, they are invariably accompanied by major developmental instability (that is, just such a dismantling of developmental homeostasis). The idea that morphological stasis is primarily a result of developmental homeostasis, and that speciation must therefore involve the temporary dismantling of such a homeostatic system,

differs from most conventional neo-Darwinian assumptions about the way in which species arise. Most neo-Darwinists would agree with Darwin's statement that new species arise 'solely by accumulating slight, successive, favourable variations'. They believe that the intrapopulation micro-evolutionary changes observed in the Drosophila cage can be simply extrapolated into the differences between Drosophila species and Dipteran families. In this view of speciation, as Gould says, there is a 'seamless continuum' a 'smooth extrapolation . . . from base substitution to the origin of higher taxa'. There is no suspicion here that the fundamental developmental constraints implied by longterm geographical and temporal stasis of species must be dismantled when new species arise. There is no suspicion that this radical reorganization of fundamental homeostatic mechanisms during speciation must involve a more radical overhaul of the phenotype than the steady 'march of metric means' seen in a Drosophila cage experiment.

Interestingly enough, the idea that disruption of developmental homeostasis, or constraints, is central to the speciation process is hardly new to the neo-Darwinian literature: Carson<sup>10</sup> has postulated 'open' and 'closed' genetic systems, the former involved in the alleleshuffling of minor adaptive adjustments within species populations, and the latter involved in the more profound regulatory

and developmental changes during speciation. Levin<sup>11</sup> has pointed out the significance of developmental disruption and instability during the speciation process. But such suggestions have been largely ignored: the implied decoupling of micro-evolutionary change and macroevolutionary phenomenon threatens the reductionist core of conventional neo-Darwinism.

The Turkana Basin sequence records a pattern of long-term stasis punctuated by rapid speciation accompanied by pronounced developmental instability. Jones suggests that this pattern requires no change in conventional views of the genetic mechanisms of the origin of species despite the fact that this pattern is neither predicted by neo-Darwinism nor explicable in terms of its major tenets. Punctuationists suggest that it is time for conventional neo-Darwinism to address the important issues of morphological stasis and developmental constraint.

#### Life on an oily wave

from A.J. Southward

AFTER three years of deliberation, the Royal Commission on Environmental Pollution has decided that chronic and accidental spills of petroleum do not pose a permanent threat to marine life comparable with the dangers inherent in heavy metals and radioactivity (Nature 293, 692; 1981). This view, with which many scientists concur, is based on the assumption that petroleum is degraded by physical, chemical and biological breakdown, and thus does not have a cumulative effect. Nevertheless, there is still public concern about oil in the environment because it is so evident, whether fouling the shoreline or killing sea-birds. Scientists too are concerned about the extent to which marine communities are disturbed by oil, and how long they take to return to normal. In consequence, a meeting\* was held recently to discuss the long term effects of oil pollution on marine populations, communities and

ecosystems. There was considerable disagreement about the importance of sublethal effects; the length of time needed for recovery; and whether the effects of pollution can be detected when natural communities show extensive short and long term fluctuations in abundance and species composition. However, some concensus was reached that planktonic and pelagic communities have been relatively untouched by oil pollution (J. Davenport. Marine Science Laboratories, University College of North Wales). This and evidence that even badly affected salt marsh communities can begin recovery after improvements to refinery effluents (B. Dicks, Orielton Field Centre, Pembroke) allowed cautious optimism about the future.

The first contribution set the scene by describing the origins and fates of the estimated six billion tons of oil that reaches

<sup>\*</sup>Discussion meeting at the Royal Society, 28–29 October 1981, organized by Dr. H. A. Cole & Professor R. B. Clark. A full report is to be published in *Phil. Traver. R. Soc. B*.

A.J. Southward is at the Marine Biological Association of the United Kingdom in Plymouth.

the sea each year (K.J. Whittle, MAFF Torry Research Station, Aberdeen). None of the following contributors who described the biological effects of oil defined what they meant by 'long term' and it was left to the penultimate speaker, Sir Hans Kornberg, FRS (Chairman Emeritus of the Royal Commission on Pollution) to quantify this term when he referred to the preceding papers as discussing "serious short term effects". Evidently the Royal Commission must regard long term as periods greater than the 10 to 20 years mentioned during the meeting as the time needed for recovery by some ecosystems after oil spills. In contrast, most of the contributors evidently thought that 10 to 20 years was a long time in comparison with the severe mortalities that ensue a few hours or days after major and minor spills (J.H. Vandermeulen, Bedford Institute of Oceanography, Dartmouth, N.S.).

It was suggested that repeated oil spills on one coast, such as in Brittany since 1967, might put off final recovery of affected communities to the next century (A.J. Southward, Marine Biological Association, Plymouth), but this was thought too pessimistic by the chairman (R.B. Clark, University of Newcastle) who noted that communities and ecosystems were remarkably resilient. This appears to be true for sea-birds, which suffer the most distressing casualties seen by the public, but which are mostly long-lived species undergoing heavy natural mortality each year, when hundreds of thousands die compared with tens of thousands killed by oil (G.M. Dunnett, University of Aberdeen). As confirmed in the discussion (W.R.P. Bourne, University of Aberdeen), some species can make up for heavy mortality in colonies by accelerated maturation of the juveniles.

Marine fishes suffer much heavier

natural mortalities than birds during their life history, and are also subjected to heavy pressure from fisheries. Fish populations, and catches by fishermen, undergo extensive natural fluctuations which, without the records of fishery statistics, might be ascribed to pollution rather than to natural changes or overfishing (R. Jones, DAFS Marine Laboratory, Aberdeen). Other marine populations, inleuding those on the seashore, undergo extensive natural fluctuations, and it may be difficult to detect pollution effects (J.R. Lewis, Wellcome Marine Laboratory, Robin Hood's Bay, Yorkshire). No general signs of oil-induced mortalities have been detected in commercial fish stocks (A.D. McIntyre, DAFS Marine Laboratory, Aberdeen), but tainting of the flesh may be evident after spills, and there is some suggestion of local inshore population changes in oysters and shrimp, related to chronic oil pollution. Other shellfish, especially Mytilus, are well known to be sensitive to low levels of petroleum hydrocarbons or other forms of sublethal environmental stress (B.L. Bayne, Institute for Marine Environmental Research, Plymouth), which can be detected as changes in metabolism and gonad development. It is therefore surprising that little general effect of natural oil seeps can be demonstrated in the Mytilus californianus community around Santa Barbara (Dale Straughan, Institute for Marine and Coastal Studies, University of Southern California, Los Angeles). Offshore petroleum operations in the Gulf of Mexico also appear to have had little effect on shell fisheries and the bottom fauna in general (J.M. Sharp, Gulf Universities Research Consortium, Houston), but signs of pollution-induced changes in the benthos are appearing close to a North Sea oil-rig (J.P. Hartley, Orielton Field

Centre, Pembroke).

Nevertheless, there is abundant experimental and circumstantial evidence that oil pollution is associated with histopathological lesions in fish and genetical abnormalities in pelagic eggs and larval stages (C.J. Sindermann, NOAA, Sandy Hook Laboratory, New Jersey). Such effects were seen in flatfish after the 'Amoco Cadiz' spill in Brittany (M. Conan, CNEXO, Brest), where long-lasting retention of oil in fine sediments may be delaying recovery of benthic animals and salt-marshes. It was thought that some saltmarshes, which were damaged by clean-up measures as well as oil, may take 20 years to recover. Comparable lengths of time have been suggested for tropical mangrove communities, which are very sensitive to oil damage (J. Baker, Orielton Field Centre, Pembroke). Both these types of community tend to be in places where oil spills are more likely.

The meeting demonstrated that there are long term chronic effects of oil, even if the evidence is partly circumstantial; but although damage from accidental spills can be severe and take many years to repair, the general effects are not as bad as once feared. It was felt that the tendency for committees to recommend further experiments on detection of effects of oil pollution should be resisted and replaced with ecological monitoring having well defined motives and objectives: there should be no hesitation in abandoning or reducing surveys where no ill effects were apparent. It is hoped that the recommendations of the Royal Commission will be acted upon by the Government, particularly those concerned with the prevention of oil spills, searches for clean-up techniques not dependent on chemicals and the setting-up of a central unit for coordinating action after spill.

#### WEATHER FORECASTS

I have recently designed and patented "An improved floating vessel for automatically compressing air by the action of the waves of the sea, and also for the generation of electricity by the agency of this compressed air." This vessel is capable of being moored in 1000 fathoms and can be connected with the shore by means of an insulated electric cable. Such a vessel moored in the mid-Atlantic in the usual track of the cyclones which approach these islands from the west, would be of immense advantage to the Meteorological Office in determining the velocity of advance and direction taken by these cyclonic centres. I purpose exhibiting a model and drawings of the vessel at the Winter Electric Exhibition, to be held at the Westminster Aquarium next CHARLES W. HARDING month.

#### THE MAGNETIC STORM AND AURORA

The telegraphic system of this country has. since Friday morning last, been disturbed in a way that far exceeds anything of the kind that has ever happened before. Very powerful electric currents have been swaying backwards and forwards through the crust of the earth, taking all telegraphic circuits in their progress, and entirely stopping communication. Communication has been maintained only where it was possible to loop together two wires, so as to avoid the use of the earth altogether. The electric storm commenced on Thursday, but it reached its climax on Friday morning (November 17) between 10 and 11 a.m. The currents measured over 50 milliampères, which is five times greater than the ordinary working currents. They have repeated themselves at intervals ever since, but have scarcely attained such an intensity as on Friday morning.

Both the storm and the aurora seem to have extended to America; the Philadelphia correspondent of the *Times* telegraphs under date November 19:—

"The electrical storm which began to derange the telegraph wires on Friday last still continues, though with less intensity. It spread through Canada and the greater part of the United States, as far west as Utah. The electricians say that the disturbance was unlike any heretofore known, acting upon the wires in strong waves, which produced constant changes in the polarity of the current. A magnificent aurora appeared on Friday night and was visible at all points, except where clouds obscured it. Cold weather, with snow, accompanied the storm in many places."

Mr W.H.M. Christie, the Astronomer Royal, writes —

In the evening, as soon as it was dark, a brilliant aurora was seen, commencing with a bright glow of red light extending from the north and west beyond the zenith, interspersed with pale green phosphorescent light and streamers. At 6h. 4m. a very brilliant streak of greenish light about 20° long appeared in the east-north-east, and, rising slowly, passed nearly along a parallel of declination, a little above the moon, disappearing at 6h. 5m. 59s. in the west, about two minutes after it was first seen. The whole aurora had faded away by about 7h., but it burst out again at 11h. 45m., when an auroral arch, with brilliant streamers reaching nearly to the zenith, was seen from north-north-east to north-west.

#### REVIEW ARTICLE

# λ Repressor and cro—components of an efficient molecular switch

Alexander D. Johnson\*, Anthony R. Poteete\*\*, Gail Lauer\*, Robert T. Sauer\*, Gary K. Ackers\* & Mark Ptashne\*

\* The Biological Laboratories, Harvard University, Cambridge, Massachusetts 02138, WSA ‡ Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA § Department of Biology and McCollum-Pratt Institute, The Johns Hopkins University, Baltimore, Maryland 21218, USA

In a lysogen, most genes of phage  $\lambda$  are repressed; in response to a transient induction signal, they are efficiently switched on. The switch, which consists in part of a tripartite operator to which two regulatory proteins bind, depends not only on DNA-protein interactions, but also on effects transmitted from one DNA-bound protein to another.  $\lambda$  exemplifies a strategy that facilitates efficient switching between two physiological states in response to a transient signal.

THE genome of the temperate bacteriophage  $\lambda$  can exist in either of two states. Switching from one state (lysogeny) to the other (lytic growth) is induced with high efficiency by external agents such as UV light, and virtually all lysogens in a population can be induced synchronously by such treatments. The genes cI and cro, upon which lysogeny and lytic growth respectively depend, encode key components of the system. The protein product of each of these genes (repressor and cro) turns off the other gene. In a lysogen, repressor is made, but not cro; after the switch to the lytic cycle, cro but not repressor is synthesized (Fig. 1).

We have recently described the molecular mechanisms of action of repressor and cro¹. These two DNA-binding proteins recognize the same operator sites but have opposite physiological effects. The action of repressor is particularly elaborate: it regulates transcription both positively and negatively and, in doing so, engages in three different cooperative interactions. Why is the action of repressor so complex?

To explore this and related questions, we first review present knowledge of how  $\lambda$  repressor and cro function. We then consider studies, largely unpublished, of 434 and P22, two other temperate phages which have represssors, cro proteins and operators that differ in sequence from those of  $\lambda$ . We find that the general structures of the operators, the patterns of positive and negative control and the types of cooperativity shown by the repressor are similar in all three phages despite protein and DNA sequence differences and differences in detailed mechanism. We argue that these common features serve the same vital role for each of the three phages: they ensure stable lysogeny and allow efficient switching to lytic growth on induction. Thus, the lytic genes of the phage are very tightly repressed in the lysogenic state, yet they are efficiently and irreversibly switched on by a transient induction signal. Such a 'hairtrigger' response would be difficult to achieve with a repressor-operator system, such as that found in the lactose operon, that lacks the cooperative features of the  $\lambda$  system.

#### λ Repressor

Phage  $\lambda$  bears two operators to which repressor and cro bind. Here we consider mainly the right operator  $(O_R)$ , the primary locus of the lysogen-lytic growth switch. This operator consists of three sites, each of which can bind either repressor or cro, but not both simultaneously. These operator sites control two divergent promoters,  $P_R$  and  $P_{RM}$  (see Fig. 2). The activity of each of these promoters depends on which of the three operator sites are occupied by repressor and/or cro. For example, at  $O_R$  a

† Present address: Department of Microbiology, University of Massachusetts Medical School, Worcester, Massachusetts 01605, USA.

prophage bears repressors bound mainly to sites  $O_{\rm R}1$  and  $O_{\rm R}2$ . In this state, repressor turns off transcription from  $P_{\rm R}$  and turns on transcription from  $P_{\rm RM}$ . As a consequence, the genes required for lytic growth (including cro) are repressed, while the gene required to maintain the lysogenic state (cI) is active. Repressor is a positive as well as a negative regulator: in its absence  $P_{\rm RM}$  functions very inefficiently. The experiments that elucidated the effect on gene transcription of repressor or crobound to each of the three sites in  $O_{\rm R}$  are described elsewhere  $^{1-7}$ .

Figure 3a shows a molecular model of the topography of repressors at  $O_R1$  and  $O_R2$  and RNA polymerase at  $P_{RM}$  in a  $\lambda$  lysogen. Three sets of protein-protein interactions are implicit in the figure: (1) dimer formation by repressor; (2) interaction between repressor dimers bound to  $O_R1$  and  $O_R2$ ; and (3) interaction between a repressor dimer bound at  $O_R2$  and an RNA polymerase molecule at  $P_{RM}$ . We shall consider these three different cooperative interactions in turn.

Formation of dimers.  $\lambda$  Repressor monomers are in equilibrium with dimers, but only dimers bind tightly to the operator<sup>8-10</sup>. One dimer occupies one operator site. Repressor monomers (236 amino acids) consist of two structural domains, each encompassing  $\sim 100$  amino acids, joined by a protease-sensitive connector<sup>11</sup>. The amino-terminal domains recognize the operator sites and the carboxy-terminal domains provide the most important contacts for dimer formation<sup>11,12</sup>. The binding in vitro of repressor to a single operator site has a sigmoidal dependence on repressor concentration, reflecting the requirement for dimer formation<sup>10,13</sup>.

Interactions between adjacent repressor dimers. Repressor dimers do not bind independently to the three sites in  $O_R$ ; rather

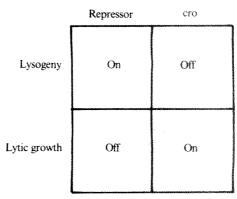

Fig. 1 Alternate physiological states of  $\lambda$ . In a lysogen, repressor is made but cro is not. During the early stages of lytic growth, cro protein but not repressor, is synthesized.
